Internet-Draft

Intended status: Standards Track March 20, 2014

Expires: September 21, 2014

Extended Administrative Groups in MPLS-TE draft-ietf-mpls-extended-admin-group-04

Abstract

MPLS-TE advertises 32 administrative groups (commonly referred to as "colors" or "link colors") using the Administrative Group sub-TLV of the Link TLV. This is defined for OSPFv2 ($\frac{RFC3630}{RFC5305}$).

This document adds a sub-TLV to the IGP TE extensions, "Extended Administrative Group". This sub-TLV provides for additional administrative groups (link colors) beyond the current limit of 32.

Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119 [RFC2119].

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of $\frac{BCP}{78}$ and $\frac{BCP}{79}$.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at http://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on September 21, 2014.

Introduction

Do we need more than 32 bits?

The IGP extensions to support MPLS-TE (RFCs 3630 [RFC3630] and 5305 [RFC5305]) define a link TLV known as Administrative Group (AG) with a limit of 32 AGs per link. The concept of Administrative Groups comes from section 6.2 of RFC 2702 [RFC2702], which calls them Resource Classes. RFCs 3630 [RFC3630] and 5305 [RFC5305] describe the mechanics of the TLV and use the term Administrative Groups (sometimes abbreviated herein as AGs), as does this document.

Networks have grown over time, and MPLS-TE has grown right along with them. Administative Groups as are advertised as a fixed-length 32-bit bitmask. This can be quite constraining, as it is possible to run out of vaues rather quickly. One such use case is #5 in Section 6.2 of RFC 2702 [RFC2702], using AGs to constrain traffic within specific topological regions of the network. A large network may well have far more than 32 geographic regions. One particular operator builds their network along the lines of this use case, using

AGs to flag network regions down to the metro scale, e.g. Seattle, San Francisco, Dallas, Chicago, St. Louis, etc. MPLS-TE tunnels are then specified with affinities to include or exclude specific metro regions in their path calculation. Each metro region is given its own bit in the AG bitmask. This means that 32 bits can only (cleanly) represent 32 metro areas. It should be obvious that 32 may not be enough even for a US-based network, nevermind a worldwide network.

There may be some opportunity for color reuse; that is, bit 0x8 may mean 'Seattle' or 'Prague' or 'Singapore' depending on the geography in which it is used. In practice, coordinating this reuse is fraught with peril and the reuse effectively becomes the limiting factor in MPLS-TE deployment. With this example it is not possible to build an LSP which avoids Seattle while including Prague, as it is the same AG value.

This document provides Extended Administrative Groups (EAGs). The number of EAGs has no fixed limit, it is constrained only by protocol-specific restrictions such as LSA or MTU size. While an operator may one day need to go beyond these protocol-specific restrictions, allow for an arbitrary number of EAGs should easily provide the operator with hundreds or thousands of bit values, thus no longer making the number of AGs an impediment to network growth.

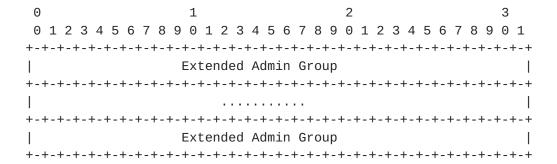

2. Extended Administrative Groups sub-TLV

The Extended Administrative Groups sub-TLV is used in addition to the Administrative Groups when a node wishes to advertise more than 32 colors for a link. The EAG sub-TLV is optional. Coexistence of EAG and AG TLVs is covered in Section 2.3.1 of this document.

This document uses the term 'colors' as a shorthand to refer to particular bits with an AG or EAG. The examples in this document use 'red' to represent the least significant bit in the AG (red == 0x1), 'blue' to represent the second bit (blue == 0x2). To say that a link has a given color or that the specified color is set on the link is to say that the corresponding bit or bits in the link's AG are set to 1.

2.1. Packet Format

The format of the Extended Administrative Groups sub-TLV is the same for both OSPF and ISIS:

The Type of the sub-TLV for OSPF and ISIS is TBD. The Length is the size of the Extended Admin Group (EAG) value in bytes. The EAG may be of any length, but MUST be a multiple of 4 bytes. The only limits on EAG size are those which are imposed by protocol-specific or media-specific constraints (e.g. max packet length).

2.2. Admin group numbering

By convention, the existing Administrative Group TLVs are numbered 0 (LSB) to 31 (MSB). The EAG values are a superset of AG. That is, bits 0-31 in the EAG have the same meaning and MUST have the same values as an AG flooded for the same link. If an EAG's length is more than 4 bytes, numbering for these additional bytes picks up where the previous byte left off. For example, the least significant bit in the 5th byte of an 8-byte EAG is referred to as bit 32.

2.3. Backward compatability

There are two questions to consider for backward compatibility with existing AG implementations - how do AG and EAG coexist, and what happens if a node has matching criteria for unadvertised EAG bits?

2.3.1. AG and EAG coexistence

If a node advertises EAG it MAY also advertise AG.

If a node advertises both AG and EAG then the first 32 bits of the EAG MUST be identical to the advertised AG. If a receiving node notices that the AG differs from the first 32 bits of the EAG, it SHOULD use the AG as the first 32 bits of the EAG, and SHOULD indicate this mismatch to the operator.

If the AG and EAG advertised for a link differ, the EAG MUST take priority. This allows nodes which do not support EAG to obtain some link color information from the network, but also allow for an eventual migration away from AG.

2.3.2. Desire for unadvertised EAG bits

The existing AG sub-TLV is optional; thus a node may be configured with a preference to include red or exclude blue, and be faced with a link that is not advertising a value for either blue or red. What does an implementation do in this case? It shouldn't assume that red is set, but it is also arguably incorrect to assume that red is NOT set, as a bit must first exist before it can be set to 0.

Practically speaking this has not been an issue for deployments, as many implementations always advertise the AG bits, often with a default value of 0x00000000. However, this issue may be of more concern once EAGs are added to the network. EAGs may exist on some nodes but not others, and the EAG length may be longer for some links than for others.

Each implementation is free to choose its own method for handling this question. However, to allow for maximum interoperability an implementation MUST treat desired but unadvertised EAG bits as if they are set to 0. Consider the case where a node wants to only use links where the 127th bit of an EAG is set to 1. If a link is only advertising 64 EAG bits, clearly the 127th EAG bit is not defined that is, it is neither explicitly 0 nor 1. The node which wants the 127th EAG bit to be 1 MUST NOT use this link, as the assumption is than an unadvertised bit is set to 0.

A node MAY provide other strategies for handling this case. A strategy which deviates from the recommended behavior in this document SHOULD be configurable, in order to provide maximum interoperability.

3. Signaling Extended Administrative Groups in RSVP

RSVP provides the ability to signal link affinity via the SESSION_ATTRIBUTE object with C-Type 1 in RFC 3209 [RFC3209]. Signaling EAG in RSVP is not addressed in this document. This document does not preclude addressing this in the future should it be deemed necessary.

4. Security Considerations

This extension adds no new security considerations.

5. IANA Considerations

This document requests a sub-TLV allocation in both OSPF and ISIS. For OSPF, the name space is "Types for sub-TLVs of TE Link TLV (Value 2)" in the "Open Shortest Path First (OSPF) Traffic Engineering

TLVs". For ISIS, it is "Sub-TLVs for TLV 22, 141, and 222" in the "IS-IS TLV Codepoints" registry. For IS-IS the value should be marked 'y' for Sub-TLVs 22, 141 and 222; this is identical to the allocation for the Administrative Group sub-TLV (value 3). In both registries the first free value should be assigned. As of this writing, that's 26 in the OSPF registry and 14 in the IS-IS registry.
