**YANG Data Model for MPLS LDP and mLDP**  
**draft-ietf-mpls-ldp-mldp-yang-00**

**Abstract**

This document describes a YANG data model for Multi-Protocol Label Switching (MPLS) Label Distribution Protocol (LDP) and Multipoint LDP (mLDP).

**Status of This Memo**

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on February 19, 2017.

Authors' Addresses . . . . . [113](#)

## [1. Introduction](#)

The Network Configuration Protocol (NETCONF) [[RFC6241](#)] is one of the network management protocols that defines mechanisms to manage network devices. YANG [[RFC6020](#)] is a modular language that represents data structures in an XML tree format, and is used as a data modelling language for the NETCONF.

This document introduces a YANG data model for MPLS Label Distribution Protocol (LDP) [[RFC5036](#)] and Multipoint LDP (mLDP) [[RFC6388](#)]. For LDP, it also covers LDP IPv6 [[RFC7552](#)] and LDP capabilities [[RFC5561](#)].

The data model is defined for following constructs that are used for managing the protocol:

- o Configuration
- o Operational State
- o Executables (Actions)
- o Notifications

This document is organized to define the data model for each of the above constructs (configuration, state, action, and notifications) in the sequence as listed earlier. Given that mLDP is tightly coupled with LDP, mLDP data model is defined under LDP tree and in the same sequence as listed above.

## [2. Specification of Requirements](#)

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [[RFC2119](#)].

In this document, the word "IP" is used to refer to both IPv4 and IPv6, unless otherwise explicitly stated. For example, "IP address family" means and be read as "IPv4 and/or IPv6 address family"

## [3. LDP YANG Model](#)

### [3.1. Overview](#)

This document defines a new module named "ietf-mpls-ldp" for LDP/mLDP data model where this module augments /rt:routing/rt:control-plane-protocols that is defined in [[I-D.ietf-netmod-routing-cfg](#)].

There are four main containers in "ietf-mpls-ldp" module as follows:

- o Read-Write parameters for configuration (Discussed in [Section 3.2](#))
- o Read-only parameters for operational state (Discussed in [Section 3.3](#))
- o Notifications for events (Discussed in [Section 3.4](#))
- o RPCs for executing commands to perform some action (Discussed in [Section 3.5](#))

For the configuration and state data, this model follows the similar approach described in [[I-D.openconfig-netmod-opstate](#)] to represent the configuration (intended state) and operational (applied and derived) state. This means that for every configuration (rw) item, there is an associated (ro) item under "state" container to represent the applied state. Furthermore, protocol derived state is also kept under "state" tree corresponding to the protocol area (discovery, peer etc.). [Ed note: This document will be (re-)aligned with [[I-D.openconfig-netmod-opstate](#)] once that specification is adopted as a WG document]

Following diagram depicts high level LDP yang tree organization and hierarchy:

```

module: ietf-mpls-ldp
  +-+ rw routing
    +-+ rw control-plane-protocols
      +-+ rw mpls-ldp
        +-+ rw global
          |   +-+ rw config
          |   +-+ ro state
          |   +-+ ro ...
          |
          |
          +-+ rw ...
          |
          |
          +-+ rw ...
          ...
          ...

rpcs:
  +-+ x mpls-ldp-rpc
  +-+ x . . . .

notifications:
  +--- n mpls-ldp-notif
  +--- n ...

```

Figure 1

Before going into data model details, it is important to take note of the following points:

- o This module aims to address only the core LDP/mLDP parameters as per RFC specification, as well as some widely used and deployed non-RFC features (such as label policies, session authentication etc). Any vendor specific feature should be defined in a vendor-specific augmentation of this model.
- o Multi-topology LDP [[RFC7307](#)] and Multi-topology mLDP [[I-D.iwijnand-mpls-mldp-multi-topology](#)] are beyond the scope of this document.
- o This module does not cover any applications running on top of LDP and mLDP, nor does it cover any OAM procedures for LDP and mLDP.
- o This model is a VPN Forwarding and Routing (VRF)-centric model. It is important to note that [[RFC4364](#)] defines VRF tables and default forwarding tables as different, however from a yang modelling perspective this introduces unnecessary complications,

Raza, et al.

Expires February 19, 2017

[Page 5]

hence we are treating the default forwarding table as just another VRF.

- o A "network-instance" as defined in [[I-D.rtyangdt-rtgwg-ni-model](#)] refers to a VRF instance (both default and non-default) within the scope of this model.
- o This model supports two address-families, namely "ipv4" and "ipv6".
- o This model assumes platform-wide label space (i.e. label space Id of zero). However, when Upstream Label assignment [[RFC6389](#)] is in use, an upstream assigned label is looked up in a Context-Specific label space as defined in [[RFC5331](#)].
- o The label and peer policies (including filters) are defined using a prefix-list. When used for a peer policy, the prefix refers to the LSR Id of the peer. The prefix-list is referenced from routing-policy model as defined in [[I-D.ietf-rtgwg-policy-model](#)].
- o The use of grouping (templates) for bundling and grouping the configuration items is not employed in current revision, and is a subject for consideration in future.
- o This model uses the terms LDP "neighbor"/"adjacency", "session", and "peer" with the following semantics:
  - \* Neighbor/Adjacency: An LDP enabled LSR that is discovered through LDP discovery mechanisms.
  - \* Session: An LDP neighbor with whom a TCP connection has been established.
  - \* Peer: An LDP session which has successfully progressed beyond its initialization phase and is either already exchanging the bindings or is ready to do so.

It is to be noted that LDP Graceful Restart mechanisms defined in [[RFC3478](#)] allow keeping the exchanged bindings for some time after a session goes down with a peer. We call such a state -- i.e. keeping peer bindings without established or recovered peering -- a "stale" peer. When used in this document, the above terms will refer strictly to the semantics and definitions defined for them.

A graphical representation of LDP YANG data model is presented in Figure 3, Figure 5, Figure 11, and Figure 12. Whereas, the actual model definition in YANG is captured in [Section 6](#).

Raza, et al.

Expires February 19, 2017

[Page 6]

While presenting the YANG tree view and actual .yang specification, this document assumes the reader is familiar with the concepts of YANG modeling, its presentation and its compilation.

### **3.2. Configuration**

This specification defines the configuration parameters for base LDP as specified in [[RFC5036](#)] and LDP IPv6 [[RFC7552](#)]. Moreover, it incorporates provisions to enable LDP Capabilities [[RFC5561](#)], and defines some of the most significant and commonly used capabilities such as Typed Wildcard FEC [[RFC5918](#)], End-of-LIB [[RFC5919](#)], and LDP Upstream Label Assignment [[RFC6389](#)].

This specification supports VRF-centric configuration. For implementations that support protocol-centric configuration, with provision for inheritance and items that apply to all vrf's, we recommend an augmentation of this model such that any protocol-centric or all-vrf configuration is defined under their designated containers within the standard network-instance (please see [Section 3.2.2](#))

This model augments /rt:routing/rt:control-plane-protocols that is defined in [[I-D.ietf-netmod-routing-cfg](#)]. For LDP interfaces, this model refers the MPLS interface as defined under MPLS base specification [[I-D.saad-mpls-base-yang](#)]. Furthermore, as mentioned earlier, the configuration tree presents read-write intended configuration leave/items as well as read-only state of the applied configuration. The former is listed under "config" container and latter under "state" container.

Following is high-level configuration organization for LDP/mLDP:

```

module: ietf-mpls-ldp
  +-+ routing
    +-+ control-plane-protocols
      +-+ mpls-ldp
        +-+ global
          |   +-+ ...
          |   +-+ ...
          |   +-+ address-family* [afi]
          |   +-+ ...
          |   +-+ ...
          |   +-+ discovery
          |   +-+ ...
        +-+ peers
          +-+ ...
          +-+ ...

```

Figure 2

Given the configuration hierarchy, the model allows inheritance such that an item in a child tree is able to derive value from a similar or related item in one of the parent. For instance, hello holdtime can be configured per-VRF or per-VRF-interface, thus allowing inheritance as well flexibility to override with a different value at any child level.

Following is a simplified graphical representation of the data model for LDP configuration

```

++-rw mpls-ldp!

Figure 3

### **3.2.1. Configuration Hierarchy**

The LDP configuration container is logically divided into following high-level config areas:

Raza, et al.

Expires February 19, 2017

[Page 11]

```
Per-VRF parameters
  o Global parameters
  o Per-address-family parameters
  o LDP Capabilities parameters
  o Hello Discovery parameters
    - interfaces
      - Per-interface:
        Global
        Per-address-family
    - targeted
      - Per-target
  o Peer parameters
    - Global
    - Per-peer
      Per-address-family
      Capabilities parameters
  o Forwarding parameters
```

Figure 4

Following subsections briefly explain these configuration areas.

### **3.2.1.1. Per-VRF parameters**

LDP module resides under an network-instance and the scope of any LDP configuration defined under this tree is per network-instance (per-VRF). This configuration is further divided into sub categories as follows.

#### **3.2.1.1.1. Per-VRF global parameters**

There are configuration items that are available directly under a VRF instance and do not fall under any other sub tree. Example of such a parameter is LDP LSR id that is typically configured per VRF. To keep legacy LDP features and applications working in an LDP IPv4 networks with this model, this document recommends an operator to pick a routable IPv4 unicast address as an LSR Id.

#### **3.2.1.1.2. Per-VRF Capabilities parameters**

This container falls under global tree and holds the LDP capabilities that are to be enabled for certain features. By default, an LDP capability is disabled unless explicitly enabled. These capabilities are typically used to negotiate with LDP peer(s) the support/non-support related to a feature and its parameters. The scope of a capability enabled under this container applies to all LDP peers in the given VRF instance. There is also a peer level capability

container that is provided to override a capability that is enabled/specify at VRF level.

#### **3.2.1.1.3. Per-VRF Per-Address-Family parameters**

Any LDP configuration parameter related to IP address family (AF) whose scope is VRF wide is configured under this tree. The examples of per-AF parameters include enabling LDP for an address family, prefix-list based label policies, and LDP transport address.

#### **3.2.1.1.4. Per-VRF Hello Discovery parameters**

This container is used to hold LDP configuration related to Hello and discovery process for both basic (link) and extended (targeted) discovery.

The "interfaces" is a container to configure parameters related to VRF interfaces. There are parameters that apply to all interfaces (such as hello timers), as well as parameters that can be configured per-interface. Hence, an interface list is defined under "interfaces" container. The model defines parameters to configure per-interface non AF related items, as well as per-interface per-AF items. The example of former is interface hello timers, and example of latter is enabling hellos for a given AF under an interface.

The "targeted" container under a VRF instance allows to configure LDP targeted discovery related parameters. Within this container, the "target" list provides a mean to configure multiple target addresses to perform extended discovery to a specific destination target, as well as to fine-tune the per-target parameters.

#### **3.2.1.1.5. Per-VRF Peer parameters**

This container is used to hold LDP configuration related to LDP sessions and peers under a VRF instance. This container allows to configure parameters that either apply on VRF's all peers or a subset (peer-list) of VRF peers. The example of such parameters include authentication password, session KA timers etc. Moreover, the model also allows per-peer parameter tuning by specifying a "peer" list under the "peers" container. A peer is uniquely identified using its LSR Id and hence LSR Id is the key for peer list

Like per-interface parameters, some per-peer parameters are AF-agnostic (i.e. either non AF related or apply to both IP address families), and some that belong to an AF. The example of former is per-peer session password configuration, whereas the example of latter is prefix-list based label policies (inbound and outbound) that apply to a given peer.

### 3.2.1.1.6. Per-VRF Forwarding parameters

This container is used to hold configuration used to control LDP forwarding behavior under a VRF instance. One example of a configuration under this container is when a user wishes to enable neighbor discovery on an interface but wishes to disable use of the same interface as forwarding nexthop. This example configuration makes sense only when there are more than one LDP enabled interfaces towards the neighbor.

### 3.2.2. All-VRFs Configuration

[Ed note: TODO]

### 3.3. Operational State

Operational state of LDP can be queried and obtained from read-only state containers that fall under the same tree (/rt:routing/rt:control-plane-protocols/) as the configuration.

Please note this state tree refers both the configuration "applied" state as well as the "derived" state related to the protocol. [Ed note: This is where this model differs presently from [[I-D.openconfig-netmod-opstate](#)] and subject to alignment in later revisions]

Following is a simplified graphical representation of the data model for LDP operational state.

```

### **3.3.1. Derived States**

Following are main areas for which LDP operational "derived" state is defined:

Neighbor Adjacencies

Peer

Bindings (FEC-label and address)

Capabilities

#### **3.3.1.1. Adjacency state**

Neighbor adjacencies are per address-family hello adjacencies that are formed with neighbors as result of LDP basic or extended discovery. In terms of organization, there is a source of discovery (e.g. interface or target address) along with its associated parameters and one or more discovered neighbors along with neighbor discovery related parameters. For the basic discovery, there could be more than one discovered neighbor for a given source (interface), whereas there is at most one discovered neighbor for an extended discovery source (local-address and target-address). This is also to be noted that the reason for a targeted neighbor adjacency could be either an active source (locally configured targeted) or passive source (to allow any incoming extended/targeted hellos). A neighbor/adjacency record also contains session-state that helps highlight whether a given adjacency has progressed to subsequent session level or to eventual peer level.

Following captures high level tree hierarchy for neighbor adjacency state.

```
+--rw mpls-ldp!
  +-+rw discovery
    +-+rw interfaces

address]
      +-+ro local-address
      +-+ro adjacent-address
      . . .
      . . .
```

Figure 6

### 3.3.1.2. Peer state

Peer related derived state is presented under peers tree. This is one of the core state that provides info on the session related parameters (mode, authentication, KA timeout etc.), TCP connection info, hello adjacencies for the peer, statistics related to messages and bindings, and capabilities exchange info.

Following captures high level tree hierarchy for peer state.

### [3.3.1.3. Bindings state](#)

Binding state provides information on LDP FEC-label bindings as well as address binding for both inbound (received) as well as outbound (advertised) direction. FEC-label bindings are presented as a FEC-centric view, and address bindings are presented as an address-centric view:

FEC-Label bindings:

FEC 200.1.1.1/32:

advertised: local-label 16000  
peer 192.168.0.2:0  
peer 192.168.0.3:0  
peer 192.168.0.4:0

received:

peer 192.168.0.2:0, label 16002, used-in-forwarding=Yes  
peer 192.168.0.3:0, label 17002, used-in-forwarding=No

FEC 200.1.1.2/32:

. . .

FEC 201.1.0.0/16:

. . .

Address bindings:

Addr 1.1.1.1:

advertised

Addr 1.1.1.2:

advertised

Addr 2.2.2.2:

received, peer 192.168.0.2

Addr 2.2.2.22:

received, peer 192.168.0.2

Figure 8

Note that all local addresses are advertised to all peers and hence no need to provide per-peer information for local address advertisement. Furthermore, note that it is easy to derive a peer-centric view for the bindings from the information already provided in this model.

Following captures high level tree hierarchy for bindings state.

```

++-rw mpls-ldp!
  +-rw global
    +-rw address-family* [afi]
      +-rw afi      address-family
      +-ro state
        +-ro ipv4 (or ipv6)
        +-ro bindings
          +-ro address* [address]
          | +-ro address
          | +-ro direction?   advertised-received
          | +-ro peer?       leafref
          +-ro fec-label* [fec]
            +-ro fec      inet:ipv4-prefix
            +-ro peer* [peer advertisement-type]
              +-ro peer           leafref
              +-ro advertisement-type   advertised-received
              +-ro label?         mpls:mpls-label
              +-ro used-in-forwarding? boolean

```

Figure 9

### [3.3.1.4. Capabilities state](#)

LDP capabilities state comprise two types of information - global information (such as timer etc.), and per-peer information.

Following captures high level tree hierarchy for LDP capabilities state.

```

++-rw mpls-ldp!
  +-rw global
    | +-ro state
    | +-ro capability
    | +-ro . . .
    | +-ro . . .
  +-rw peers
    +-rw peer* [lsrc-id]
      +-rw lsrc-id   yang:dotted-quad
      +-ro state
        +-ro received-peer-state
          +-ro capability
            +-ro . . .
            +-ro . . .

```

Figure 10

### **3.4. Notifications**

This model defines a list of notifications to inform client of important events detected during the protocol operation. These events include events related to changes in the operational state of an LDP peer, hello adjacency, and FEC etc. It is to be noted that an LDP FEC is treated as operational (up) as long as it has at least 1 NHLFE with outgoing label.

Following is a simplified graphical representation of the data model for LDP notifications.

```
module: ietf-mpls-ldp
notifications:
  +--n mpls-ldp-peer-event
    |  +-+ro event-type?  oper-status-event-type
    |  +-+ro peer-ref?  leafref
  +--n mpls-ldp-hello-adjacency-event
    |  +-+ro event-type?  oper-status-event-type
    |  +-+ro (hello-adjacency-type)?
    |    +--+:(targeted)
    |      |  +-+ro targeted
    |      |  +-+ro target-address?  inet:ip-address
    |    +--+:(link)
    |      +-+ro link
    |        +-+ro next-hop-interface?  mpls-interface-ref
    |        +-+ro next-hop-address?  inet:ip-address
  +--n mpls-ldp-fec-event
    +-+ro event-type?  oper-status-event-type
    +-+ro prefix?  inet:ip-prefix
```

Figure 11

### **3.5. Actions**

This model defines a list of rpcs that allow performing an action or executing a command on the protocol. For example, it allows to clear (reset) LDP peers, hello-adjacencies, and statistics. The model makes an effort to provide different level of control so that a user is able to either clear all, or clear all for a given type, or clear a specific entity.

Following is a simplified graphical representation of the data model for LDP actions.

```

module: ietf-mpls-ldp
rpcs:
  +---x mpls-ldp-clear-peer
  |   +---w input
  |   |   +---w lsr-id?    union
  +---x mpls-ldp-clear-hello-adjacency
  |   +---w input
  |   |   +---w hello-adjacency
  |   |   +---w (hello-adjacency-type)?
  |   |   |   +---:(targeted)
  |   |   |   |   +---w targeted!
  |   |   |   |   +---w target-address?    inet:ip-address
  |   |   |   +---:(link)
  |   |   |   +---w link!
  |   |   |   +---w next-hop-interface?    mpls-interface-ref
  |   |   |   +---w next-hop-address?    inet:ip-address
  +---x mpls-ldp-clear-peer-statistics
  |   +---w input
  |   +---w lsr-id?    union

```

Figure 12

## **4. mLDP YANG Model**

### **4.1. Overview**

Due to tight dependency of mLDP on LDP, mLDP model builds on top of LDP model defined earlier in the document. Following are the main mLDP areas and documents that are within the scope of this model:

- o mLDP Base Specification [[RFC6388](#)]
- o mLDP Recursive FEC [[RFC6512](#)]
- o Targeted mLDP [[RFC7060](#)]
- o mLDP Fast-Reroute (FRR)
  - \* Node Protection [[RFC7715](#)]
  - \* Multicast-only
- o Hub-and-Spoke Multipoint LSPs [[RFC7140](#)]
- o mLDP In-band Signaling [[RFC6826](#)] (future revision)
- o mLDP In-band signaling in a VRF [[RFC7246](#)]

- o mLDP In-band Signaling with Wildcards [[RFC7438](#)] (future revision)

- o Configured Leaf LSPs (manually provisioned)

[Ed Note: Some of the topics in the above list are to be addressed/added in later revision of this document].

## **4.2. Configuration**

### **4.2.1. Configuration Hierarchy**

In terms of overall configuration layout, following figure highlights extensions to LDP configuration model to incorporate mLDP:

```
+-- mpls-ldp
  +- ...
  +- ...
  +- mldp
    |  +- ...
    |  +- ...
    |  +- address-family* [af]
      +- af
        +- ...
        +- ...
    +- global
      +- ...
      +- capability
        +- ...
        +- ...
      +- mldp
        +- ...
        +- ...
  +- discovery
    +- ...
    +- ...
  +- forwarding-nexthop
    +- interfaces
      +- interface* [interface]
        +- interface
        +- address-family* [af]
          +- af
          +- ...
        +- mldp-disable
  +- peers
    +- ...
    +- ...
    +- peer* [lsr-id]
      +- ...
      +- ...
      +- capability
        +- ...
        +- ...
      +- mldp
        +- ...
        +- ...
```

Figure 13

From above hierarchy, we can categorize mLDP configuration parameters into two types:

Raza, et al.

Expires February 19, 2017

[Page 29]

- o Parameters that leverage/extend LDP containers and parameters
- o Parameters that are mLDP specific

Following subsections first describe mLDP specific configuration parameters, followed by those leveraging LDP.

#### **4.2.2. mldp container**

mldp container resides directly under "mpls-ldp" and holds the configuration related to items that are mLDP specific. The main items under this container are:

- o mLDP enabling: To enable mLDP under a (VRF) routing instance, mldp container is enabled under LDP. Given that mLDP requires LDP signalling, it is not sensible to allow disabling LDP control plane under a (VRF) network-instance while requiring mLDP to be enabled for the same. However, if a user wishes only to allow signalling for multipoint FECs on an LDP/mLDP enabled VRF instance, he/she can use LDP label-policies to disable unicast FECs under the VRF.
- o mLDP per-AF features: mLDP manages its own list of IP address-families and the features enabled underneath. The per-AF mLDP configuration items include:
  - \* Multicast-only FRR: This enables Multicast-only FRR functionality for a given AF under mLDP. The feature allows route-policy to be configured for finer control/applicability of the feature.
  - \* Recursive FEC: The recursive-fec feature [[RFC6512](#)] can be enabled per AF with a route-policy.
  - \* Configured Leaf LSPs: To provision multipoint leaf LSP manually, a container is provided per-AF under LDP. The configuration is flexible and allows a user to specify MP LSPs of type p2mp or mp2mp with IPv4 or IPv6 root address(es) by using either LSP-ID or (S,G).

Targeted mLDP feature specification [[RFC7060](#)] do not require any mLDP specific configuration. It, however, requires LDP upstream-label-assignment capability [[RFC6389](#)] to be enabled.

#### **4.2.3. Leveraging LDP containers**

mLDP configuration model leverages following configuration areas and containers that are already defined for LDP:

- o Capabilities: A new container "mldp" is defined under Capabilities container. This new container specifies any mLDP specific capabilities and their parameters. Moreover, a new "mldp" container is also added under per-peer capability container to override/control mLDP specific capabilities on a peer level. In the scope of this document, the most important capabilities related to mLDP are p2mp, mp2mp, make-before-break, hub-and-spoke, and node-protection.
- o Discovery and Peer: mLDP requires LDP discovery and peer procedures to form mLDP peering. A peer is treated as mLDP peer only when either P2MP or MP2MP capabilities have been successfully exchanged with the peer. If a user wish to selectively enable or disable mLDP with a LDP-enabled peer, he/she may use per-peer mLDP capabilities configuration. [Ed Note: The option to control mLDP enabling/disabling on a peer-list is being explored for future ]. In most common deployments, it is desirable to disable mLDP (capabilities announcements) on a targeted-only LDP peering, where targeted-only peer is the one whose discovery sources are targeted only. In future revision, a configuration option for this support will also be provided.
- o Forwarding: By default, mLDP is allowed to select any of the LDP enabled interface as a downstream interface towards a nexthop (LDP/mLDP peer) for MP LSP programming. However, a configuration option is provided to allow mLDP to exclude a given interface from such a selection. Note that such a configuration option will be useful only when there are more than one interfaces available for the downstream selection.

This goes without saying that mLDP configuration tree follows the same approach as LDP, where the tree comprise leafs for intended configuration.

#### **4.2.4. YANG tree**

The following figure captures the YANG tree for mLDP configuration. To keep the focus, the figure has been simplified to display only mLDP items without any LDP items.

```
module: ietf-mpls-ldp
augment /rt:routing/rt:control-plane-protocols:
  +-rw mpls-ldp!
```

```
+--rw global
|  +-rw config
|  |  +-rw capability
|  |  |  +-rw mldp {mldp}?

```

Figure 14

#### **4.3. Operational State**

Operational state of mLDP can be queried and obtained from this read-only container "mldp" which resides under mpls-ldp container.

Raza, et al.

Expires February 19, 2017

[Page 33]

Please note this state tree refers both the configuration "applied" state as well as the "derived" state related to the mLDP protocol.

Following is a simplified graphical representation of the data model for mLDP operational state:

```
module: ietf-mpls-ldp
augment /rt:routing/rt:control-plane-protocols:
  +-rw mpls-ldp!

### Figure 15

#### **4.3.1. Derived states**

Following are main areas for which mLDP operational derived state is defined:

- o Root
- o Bindings (FEC-label)
- o Capabilities

#### **4.3.1.1. Root state**

Root address is a fundamental construct for MP FEC bindings and LSPs. The root state provides information on all the known roots in a given address-family, and their information on the root reachability (as learnt from RIB). In case of multi-path reachability to a root, the selection of upstream path is done on per-LSP basis at the time of LSP setup. Similarly, when protection mechanisms like MBB or MoFRR are in place, the path designation as active/standby or primary/backup is also done on per LSP basis. It is to be noted that a given root can be shared amongst multiple P2MP and/or MP2MP LSPs. Moreover, an LSP can be signaled to more than one root for RNR purposes.

The following diagram illustrates a root database on a branch/transit LSR:

```

root 1.1.1.1:
  path1:
    RIB: GigEthernet 1/0, 12.1.0.2;
    LDP: peer 192.168.0.1:0
  path2:
    RIB: GigEthernet 2/0, 12.2.0.2;
    LDP: peer 192.168.0.3:0

root 2.2.2.2:
  path1:
    RIB: 3.3.3.3;           (NOTE: This is a recursive path)
    LDP: peer 192.168.0.3:0 (NOTE: T-mLDP peer)

root 9.9.9.9:
  . . .

```

Figure 16

A root entry on a root LSR itself will be presented as follows:

```

root 9.9.9.9:
  is-self

```

Figure 17

#### 4.3.1.2. Bindings state

Binding state provides information on mLDP FEC-label bindings for both P2MP and MP2MP FEC types. Like LDP, the FEC-label binding derived state is presented in a FEC-centric view per address-family, and provides information on both inbound (received) and outbound (advertised) bindings. The FEC is presented as (root-address, opaque-type-data) and the direction (upstream or downstream) is picked with respect to root reachability. In case of MBB or/and MoFRR, the role of a given peer binding is also provided with respect to MBB (active or standby) or/and MoFRR (primary or backup).

This document covers following type of opaque values with their keys in the operational model of mLDP bindings:

Opaque Type	Key	RFC
Generic LSP Identifier	LSP Id	[ <a href="#">RFC6388</a> ]
Transit IPv4 Source	Source, Group	[ <a href="#">RFC6826</a> ]
Transit IPv6 Source	Source, Group	[ <a href="#">RFC6826</a> ]
Transit IPv4 Bidir	RP, Group	[ <a href="#">RFC6826</a> ]
Transit IPv6 Bidir	RP, Group	[ <a href="#">RFC6826</a> ]
Transit VPNv4 Source	Source, Group, RD	[ <a href="#">RFC7246</a> ]
Transit VPNv6 Source	Source, Group, RD	[ <a href="#">RFC7246</a> ]
Transit VPNv4 Bidir	RP, Group, RD	[ <a href="#">RFC7246</a> ]
Transit VPNv6 Bidir	RP, Group, RD	[ <a href="#">RFC7246</a> ]
Recursive Opaque	Root	[ <a href="#">RFC6512</a> ]
VPN-Recursive Opaque	Root, RD	[ <a href="#">RFC6512</a> ]

Table 1: MP Opaque Types and keys

It is to be noted that there are three basic types (LSP Id, Source, and Bidir) and then there are variants (VPN, recursive, VPN-recursive) on top of these basic types.

Following captures high level tree hierarchy for mLDP bindings state:

```

++-rw mpls-ldp!
  +-rw mldp
    +-rw address-family* [afi]
      +-rw afi      address-family
      +-ro state
        +-ro ipv4 (or ipv6)
          +-ro bindings
            +-ro opaque-type-xxx [root-address, type-specific-key]
              +-ro root-address
              +-ro ...
              +-ro recur-root-address    inet:ipv4-address
              +-ro recur-rd            route-distinguisher
              +-ro multipoint-type?   multipoint-type
              +-ro peer* [direction peer advertisement-type]
                +-ro direction        downstream-upstream
                +-ro peer             leafref
                +-ro advertisement-type advertised-received
                +-ro label?           mpls:mpls-label
                +-ro mbb-role?        enumeration
                +-ro mofrr-role?      enumeration

```

Figure 18

In the above tree, the type-specific-key varies with the base type as listed in earlier Table 1. For example, if the opaque type is Generic LSP Identifier, then the type-specific-key will be a uint32 value corresponding to the LSP. Please see the complete model for all other types.

Moreover, the binding tree defines only three types of sub-trees (i.e. lpid, src, and bidir) which is able to map the respective variants (vpn, recursive, and vpn-recursive) accordingly. For example, the key for opaque-type-src is [R, S, G, rd, recur-R, recur-RD], where basic type will specify (R, S, G, -, -, -), VPN type will specify (R, S, G, rd, -, -), recursive type will specify [R, S, G, -, recur-R, -] and VPN-recursive type will specify [R, S, G, -, recur-R, recur-rd].

It is important to take note of the following:

- o The address-family ipv4/ipv4 applies to "root" address in the mLDP binding tree. The other addresses (source, group, RP etc) do not have to be of the same address family type as the root.
- o The "recur-root-address" field applies to Recursive opaque type, and (recur-root-address, recur-rd) fields applies to VPN-Recursive opaque types as defined in [[RFC6512](#)]
- o In case of a recursive FEC, the address-family of the recur-root-address could be different than the address-family of the root address of original encapsulated MP FEC

The following diagram illustrates the FEC-label binding information structure for a P2MP (Transit IPv4 Source type) LSP on a branch/transit LSR:

```
FEC (root 2.2.2.2, S=192.168.1.1, G=224.1.1.1):  
  type: p2mp  
  upstream:  
    advertised:  
      peer 192.168.0.1:0, label 16000 (local)  
  downstream:  
    received:  
      peer 192.168.0.2:0, label 17000 (remote)  
      peer 192.168.0.3:0, label 18000 (remote)
```

Figure 19

The following diagram illustrates the FEC-label binding information structure for a similar MP2MP LSP on a branch/transit LSR:

```
FEC (root 2.2.2.2, RP=192.168.9.9, G=224.1.1.1):
  type: mp2mp
  upstream:
    advertised:
      peer 192.168.0.1:0, label 16000 (local)
    received:
      peer 192.168.0.1:0, label 17000 (remote)
  downstream:
    advertised:
      peer 192.168.0.2:0, label 16001 (local), MBB role=active
      peer 192.168.0.3:0, label 16002 (local), MBB role=standby
    received:
      peer 192.168.0.2:0, label 17001 (remote)
      peer 192.168.0.3:0, label 18001 (remote)
```

Figure 20

#### [4.3.1.3. Capabilities state](#)

Like LDP, mLDP capabilities state comprise two types of information - global information and per-peer information.

#### [4.4. Notifications](#)

mLDP notification module consists of notification related to changes in the operational state of an mLDP FEC. Following is a simplified graphical representation of the data model for mLDP notifications:

```
notifications:
  +-+ n mpls-mldp-fec-event
    +-+ ro event-type?          oper-status-event-type
    +-+ ro tree-type?          multipoint-type
    +-+ ro root?               inet:ip-address
    +-+ ro (lsp-key-type)?
      +-+: (lsp-id-based)
      |  +-+ ro lsp-id?         uint16
      +-+: (source-group-based)
        +-+ ro source-address?  inet:ip-address
        +-+ ro group-address?   inet:ip-address
```

#### 4.5. Actions

Currently, no RPCs/actions are defined for mLDP.

### 5. Open Items

Following is a list of open items that are to be discussed and addressed in future revisions of this document:

- o Close on augmentation off "mpls" list in "ietf-mpls" defined in [[I-D.saad-mpls-base-yang](#)]
- o Align operational state modeling with other routing protocols and [[I-D.openconfig-netmod-opstate](#)]
- o Complete the section on Protocol-centric implementations and all-vrfs
- o Specify default values for configuration parameters
- o Revisit and cut down on the scope of the document and number of features it is trying to cover
- o Split the model into a base and extended items
- o Add statistics for mLDP root LSPs and bindings
- o Extend the "Configured Leaf LSPs" for various type of opaque-types
- o Extend mLDP notifications for other types of opaque values as well
- o Close on single vs separate document for mLDP Yang

### 6. YANG Specification

Following are actual YANG definition for LDP and mLDP constructs defined earlier in the document.

```
<CODE BEGINS> file "ietf-mpls-ldp@2016-07-08.yang" -->

module ietf-mpls-ldp {
    namespace "urn:ietf:params:xml:ns:yang:ietf-mpls-ldp";
    // replace with IANA namespace when assigned
    prefix ldp;

    import ietf-inet-types {
```

```
prefix "inet";
}

import ietf-yang-types {
    prefix "yang";
}

import ietf-interfaces {
    prefix "if";
}

import ietf-ip {
    prefix "ip";
}

import ietf-routing {
    prefix "rt";
}

import ietf-mpls {
    prefix "mpls";
}

### **7. Security Considerations**

The configuration, state, action and notification data defined using YANG data models in this document are likely to be accessed via the protocols such as NETCONF [[RFC6241](#)] etc.

Hence, YANG implementations MUST comply with the security requirements specified in [section 15 of \[RFC6020\]](#). Additionally, NETCONF implementations MUST comply with the security requirements specified in sections [2.2](#), [2.3](#) and [9](#) of [[RFC6241](#)] as well as [section 3.7 of \[RFC6536\]](#).

### **8. IANA Considerations**

This document does not extend LDP or mLDP base protocol specification and hence there are no IANA considerations.

Note to the RFC Editor: Please remove IANA section before the publication.

### **9. Acknowledgments**

The authors would like to acknowledge Eddie Chami, Nagendra Kumar, Mannan Venkatesan, Pavan Beeram for their contribution to this document. We also acknowledge Ladislav Lhotka for his useful comments as the YANG Doctor.
