              Definition of Time-to-Live TLV for LSP-Ping Mechanisms
                    draft-ietf-mpls-lsp-ping-ttl-tlv-08.txt

Abstract

   LSP-Ping is a widely deployed Operation, Administration, and
   Maintenance (OAM) mechanism in MPLS networks. However, in the present
   form, this mechanism is inadequate to verify connectivity of a
   segment of a Multi-Segment PseudoWire (MS-PW) and/or bidirectional
   co-routed LSP from any node on the path of the MS-PW and/or
   bidirectional co-routed LSP. This document defines a TLV to address
   this shortcoming.

Status of this Memo

   This Internet-Draft is submitted to IETF in full conformance with the
   provisions of BCP 78 and BCP 79.

   Internet-Drafts are working documents of the Internet Engineering
   Task Force (IETF), its areas, and its working groups. Note that
   other groups may also distribute working documents as
   Internet-Drafts.

   Internet-Drafts are draft documents valid for a maximum of six months
   and may be updated, replaced, or obsoleted by other documents at any
   time. It is inappropriate to use Internet-Drafts as reference
   material or to cite them other than as "work in progress."

   The list of current Internet-Drafts can be accessed at
   http://www.ietf.org/1id-abstracts.html

   The list of Internet-Draft Shadow Directories can be accessed at

Table of Contents

1. Introduction

A MS-PW may span across multiple service provider networks. In order to allow Service Providers (SP) to verify segments of such MS-PW from any node on the path of the MS-PW, any node along the path of the MS-PW, should be able to originate an MPLS Echo Request packet to any other node along the path of the MS-PW and receive the corresponding MPLS Echo Reply. If the originator of the MPLS Echo Request is at the end of a MS-PW, the receiver of the request can send the reply back to the sender without knowing the hop-count distance of the originator. The reply will be intercepted by the originator regardless of the TTL value on the reply packet. But, if the originator is not at the end of the MS-PW, the receiver of the MPLS Echo Request MAY need to know how many hops away the originator of the MPLS Echo Request is so that it can set the TTL value on the MPLS header for the MPLS Echo Reply to be intercepted at the originator node.

In MPLS networks, for bidirectional co-routed LSPs, if it is desired to verify connectivity from any intermediate node (LSR) on the LSP to the any other LSR on the LSP the receiver may need to know the TTL to send the MPLS Echo Reply with, so as the packet is intercepted by the originator node.

A new optional TTL TLV is defined in this document. This TLV will be added by the originator of the MPLS Echo Request to inform the receiver how many hops away the originator is on the path of the MS-PW or Bidirectional LSP.

This mechanism only works if the MPLS Echo Reply is sent down the co-routed LSP, hence the scope of this TTL TLV is currently limited to MS-PW or Bidirectional co-routed MPLS LSPs. The presence of the TLV implies the use of the return path of the co-routed LSP, if the return path is any other mechanism then the TLV in the MPLS Echo Request MUST be ignored.

2. Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119 [RFC2119].

LSR: Label Switching Router

MPLS-TP: MPLS Transport Profile

MS-PW: Multi-Segment Pseudowire

PW: Pseudowire

TLV: Type Length Value

TTL: Time To Live

[3](#). Time To Live TLV

[3.1](#). TTL TLV Format

```
 0                   1                   2                   3
 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
|  Type = TBD              |  Length = 8                       |
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
|  Value       |  Reserved  |  Flags                           |
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
                Figure 1: Time To Live TLV format
```
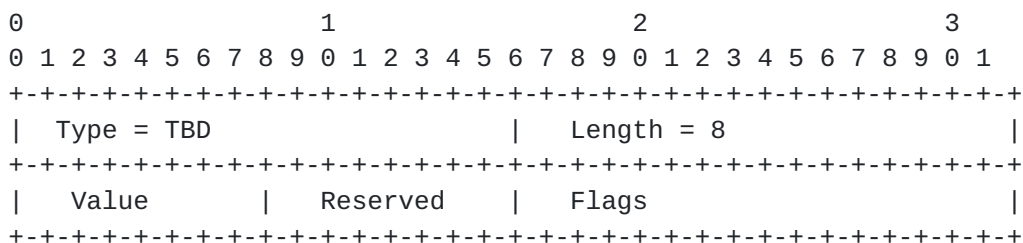

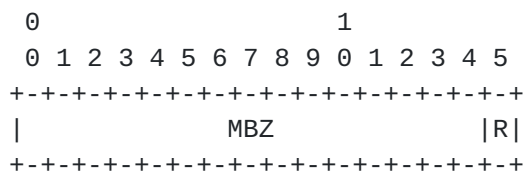

The TTL TLV has the format shown in Figure 1.

Value

The value of the TTL as specified by this TLV

Flags

The Flags field is a bit vector with the following format:

```
 0                   1
 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
|             MBZ           |R|
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
```

One flag is defined for now, the R flag; the rest of the flags are currently undefined and MUST be zero (MBZ) when sending and ignored on receipt.

The R flag (Reply TTL) is set signify that the value is meant to be used as the TTL for the reply packet. Other bits may be defined later to enhance the scope of this TLV.

[3.2](#). Usage

This TLV SHALL be included in the MPLS Echo Request by the originator

of request. The use of this TLV is optional. If a receiver does not
understand the TTL TLV, it will simply ignore the TLV (Type value of
TLV is assumed to be in the range of optional TLV's which SHOULD be
ignored if an implementation does not support or understand them). In
the absence of TTL TLV or if TTL TLV is ignored by a receiver, the
determination of the TTL value used in the MPLS label on the LSP-Ping
echo reply is beyond the scope of this document.

If a receiver understands the TTL TLV, and the TTL TLV is present in
the MPLS Echo Request, and if the value field is zero, the LSP-Ping
echo request packet SHOULD be dropped.

If a receiver understands the TTL TLV, and the TTL TLV is present in
the MPLS Echo Request, the receiver MUST use the TTL value specified
in TLV in the MPLS header of the MPLS Echo Reply. In other words, if
the value of the TTL provided by this TLV does not match the TTL
determined by other means, such as Switching Point TLV in MS-PW, then
TTL TLV MUST be used. This will aid the originator of the LSP-Ping
echo request in analyzing the return path.

4. **Operation**

In this section, we explain a use case for the TTL TLV with an MPLS
MS-PW.

```
                    <------------------MS-PW --------------------->

                    A           B          C          D          E
                    o -------- o -------- o --------- o --------- o
                              ---MPLS Echo Request--->
                              <--MPLS Echo Reply------

                        Figure 2: Use-case with MS-PWs
```
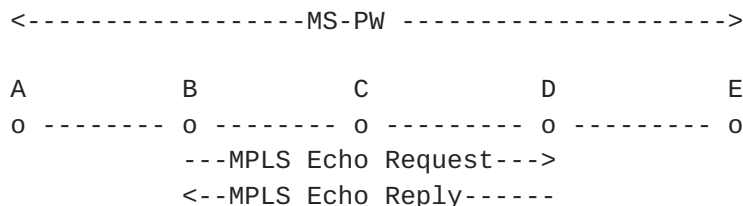

Let us assume a MS-PW going through LSRs A, B, C, D, and E.
Furthermore, assume that an operator wants to perform a connectivity
check between B and D from B. Thus, an MPLS Echo Request with the TTL
TLV is originated from B and sent towards D. The MPLS Echo Request
packet contains the FEC of the PW Segment between C and D. The value
field of the TTL TLV and the TTL field of the MPLS label are set to
2, the choice of the value 2 will be based on the operator input
requesting the MPLS Echo Request or from the optional LDP switching
point TLV. The MPLS Echo Request is intercepted at D because of TTL
expiry. D detects the TTL TLV in the request, and use the TTL value
(i.e., 2) specified in the TLV on the MPLS label of the MPLS Echo
Reply. The MPLS Echo Reply will be intercepted by B because of TTL
expiry.

The same operation will apply in the case a co-routed bidirectional
LSP and we want to check connectivity from an intermediate LSR B to
another LSR D, from B.

4.1. Traceroute mode

In the traceroute mode TTL value in the TLV is successively set to 1,
2, and so on. This is similar to the TTL values used for the label
set on the packet.

4.2. Error scenario

It is possible that the MPLS Echo Request packet was intercepted
before the intended destination for reason other than label TTL
expiry. This could be due network faults, misconfiguration or other
reasons. In such cases, if the return TTL is set to the value
specified in the TTL TLV then the echo response packet will continue
beyond the originating node. This becomes a security issue.

To prevent this, the label TTL value used in the MPLS Echo Reply
packet MUST be modified by deducting the incoming label TTL on the
received packet from TTL TLV value. If the MPLS Echo Request packet
is punted to the CPU before the incoming label TTL is deducted, then
another 1 MUST be deducted. In other words:

Return TTL Value on the MPLS Echo Reply packet = (TTL TLV Value)-
(Incoming Label TTL) + 1

5. Security Considerations

This draft allows the setting of the TTL value in the MPLS Label of
an MPLS Echo Reply, so that it can be intercepted by an intermediate
device. This can cause a device to get a lot of LSP Ping packets
which get redirected to the CPU.

However the same is possible even without the changes mentioned in
this document. A device should rate limit the LSP ping packets
redirected to the CPU so that the CPU is not overwhelmed.

The recommendation in [RFC4379] security section applies, to check
the source address of the MPLS Echo Request, however the source
address can now be any node along the LSP path.

A faulty transit node changing the TTL TLV value could make the wrong
node reply to the MPLS Echo Request, and/or the wrong node to receive
the MPLS Echo Reply. An LSP trace may help identify the faulty

transit node.

6. IANA Considerations

IANA is requested to assign TLV type value to the following TLV from the "Multiprotocol Label Switching Architecture (MPLS) Label Switched Paths (LSPs) Parameters - TLVs" registry, "TLVs and sub-TLVs" sub-registry.

Time To Live TLV (See Section 3). The value MUST be assigned from the range (32768-49161) of optional TLVs.

7. Acknowledgements

The authors would like to thank Greg Mirsky for his comments.
