RESTCONF Protocol
draft-ietf-netconf-restconf-01

Abstract

This document describes an HTTP-based protocol that provides a programmatic interface for accessing data defined in YANG, using the datastores defined in NETCONF.

Status of this Memo

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on January 4, 2015.

1. Introduction

There is a need for standard mechanisms to allow WEB applications to access the configuration data, operational data, data-model specific protocol operations, and notification events within a networking device, in a modular and extensible manner.

This document describes an HTTP [[RFC2616](#)] based protocol called RESTCONF, for accessing data defined in YANG [[RFC6020](#)], using datastores defined in NETCONF [[RFC6241](#)].

The NETCONF protocol defines configuration datastores and a set of Create, Retrieve, Update, Delete (CRUD) operations that can be used to access these datastores. The YANG language defines the syntax and semantics of datastore content, operational data, protocol operations, and notification events. RESTCONF uses HTTP operations to provide CRUD operations on a NETCONF datastore containing YANG-defined data. Since NETCONF protocol operations are not relevant, the user should not need any prior knowledge of NETCONF in order to use RESTCONF.

Configuration data and state data are exposed as resources that can be retrieved with the GET method. Resources representing configuration data can be modified with the DELETE, PATCH, POST, and PUT methods. Data is encoded with either XML [[W3C.REC-xml-20081126](#)] or JSON [[JSON](#)].

Data-model specific protocol operations defined with the YANG "rpc" statement can be invoked with the POST method. Data-model specific notification events defined with the YANG "notification" statement can be accessed.

1.1. Secure Transport

RESTCONF relies on TLS [[RFC2246](#)] to provide privacy and data integrity for its HTTP operations. More specifically, RESTCONF requires HTTP over TLS (HTTPS) [[RFC2818](#)]. To ensure security, RESTCONF clients MUST verify the RESTCONF server's X.509 certificate using the path validation algorithm defined in [section 6 of \[RFC5280\]](#). Devices that do not support TLS will be unable to implement RESTCONF.

1.2. Simple Subset of NETCONF Functionality

The framework and meta-model used for an HTTP-based API does not need to mirror those used by the NETCONF protocol, but it needs to be compatible with NETCONF. A simplified framework and protocol is needed that utilizes the three NETCONF datastores (candidate,

running, startup), but hides the complexity of multiple datastores from the client.

A simplified transaction model is needed that allows basic CRUD operations on a hierarchy of conceptual resources. This represents a limited subset of the transaction capabilities of the NETCONF protocol.

Applications that require more complex transaction capabilities might consider NETCONF instead of RESTCONF. The following transaction features are not directly provided in RESTCONF:

- o datastore locking (full or partial)
- o candidate datastore
- o startup datastore
- o validate operation
- o confirmed-commit procedure

RESTCONF is not intended to replace NETCONF, but rather provide an additional simplified interface that follows REST principles and is compatible with a resource-oriented device abstraction.

The following figure shows the system components:

1.3. Data Model Driven API

RESTCONF combines the simplicity of the HTTP protocol with the predictability and automation potential of a schema-driven API. Using YANG, a client can predict all resource endpoints, much like using URI Templates [RFC6570], but in a more holistic manner. This strategy obviates the need for responses provided by the server to contain HATEOAS links, originally described in Roy Fielding's doctoral dissertation [rest-dissertation].

A REST client using HATEOAS principles would not use any data

modeling language to define the application-specific content of the API. The client would discover each new child resource as it traverses the URIs returned as Location IDs to discover the server capabilities. This approach has 3 significant weaknesses with regards to control of complex networking devices:

- o inefficient performance: configuration APIs will be quite complex and may require thousands of protocol messages to discover all the schema information. Typically the data type information has to be passed in the protocol messages, which is also wasteful overhead.
- o no data model richness: without a data model, the schema-level semantics and validation constraints are not available to the application.
- o no tool automation: API automation tools need some sort of content schema to function. Such tools can automate various programming and documentation tasks related to specific data models.

Data model modules such as YANG modules serve as an "API contract" that will be honored by the server. An application designer can code to the data model, knowing in advance important details about the exact protocol operations and datastore content a conforming server implementation will support.

RESTCONF provides the YANG module capability information supported by the server, in case the client wants to use it. The URIs for custom protocol operations and datastore content are predictable, based on the YANG module definitions.

Operational experience with CLI and SNMP indicates that operators learn the 'location' of specific service or device related data and do not expect such information to be arbitrary and discovered each time the client opens a management session to a server.

The RESTCONF protocol operates on a conceptual datastore defined with the YANG data modeling language. The server lists each YANG module it supports under "{+restconf}/modules" in the top-level API resource type, using a structure based on the YANG module capability URI format defined in [[RFC6020](#)].

The conceptual datastore contents, data-model-specific operations and notification events are identified by this set of YANG module resources. All RESTCONF content identified as either a data resource, operation resource, or event stream resource is defined with the YANG language.

The classification of data as configuration or non-configuration is

derived from the YANG "config" statement. Data ordering behavior is derived from the YANG "ordered-by" statement.

The RESTCONF datastore editing model is simple and direct, similar to the behavior of the ":writable-running" capability in NETCONF. Each RESTCONF edit of a datastore resource is activated upon successful completion of the transaction.

1.4. Terminology

The keywords "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [BCP 14](#), [[RFC2119](#)].

1.4.1. NETCONF

The following terms are defined in [[RFC6241](#)]:

- o candidate configuration datastore
- o client
- o configuration data
- o datastore
- o configuration datastore
- o protocol operation
- o running configuration datastore
- o server
- o startup configuration datastore
- o state data
- o user

1.4.2. HTTP

The following terms are defined in [[RFC2616](#)]:

- o entity tag

- o fragment
- o header line
- o message body
- o method
- o path
- o query
- o request
- o request URI
- o response body
- o resource

1.4.3. YANG

The following terms are defined in [[RFC6020](#)]:

- o container
- o data node
- o key leaf
- o leaf
- o leaf-list
- o list
- o presence container (or P-container)
- o RPC operation (now called protocol operation)
- o non-presence container (or NP-container)
- o ordered-by system
- o ordered-by user

[1.4.4.](#) Terms

The following terms are used within this document:

- o API resource: a resource with the media type "application/yang.api+xml" or "application/yang.api+json". API resources can only be edited by the server.
- o data resource: a resource with the media type "application/yang.data+xml" or "application/yang.data+json". Data resources can be edited by clients or the server. All YANG data node types can be data resources. YANG terminal nodes cannot contain child resources.
- o datastore resource: a resource with the media type "application/yang.datastore+xml" or "application/yang.datastore+json". Represents a configuration datastore.
- o edit operation: a RESTCONF operation on a data resource using the POST, PUT, PATCH, or DELETE method.
- o event stream resource: a resource with the media type "application/yang.stream+xml" or "application/yang.stream+json". This resource represents an SSE (Server-Sent Events) event stream. The content consists of text using the media type "text/event-stream", as defined by the HTML5 specification. Each event represents one <notification> message generated by the server. It contains a conceptual system or data-model specific event that is delivered within a notification event stream.
- o operation: the conceptual RESTCONF operation for a message, derived from the HTTP method, request URI, headers, and message body.
- o operation resource: a resource with the media type "application/yang.operation+xml" or "application/yang.operation+json".
- o patch: a generic PATCH request on the target datastore or data resource. The media type of the message body content will identify the patch type in use.
- o plain patch: a PATCH request where the media type is "application/yang.data+xml" or "application/yang.data+json".
- o query parameter: a parameter (and its value if any), encoded within the query component of the request URI.

- o retrieval request: a request using the GET or HEAD methods.
- o target resource: the resource that is associated with a particular message, identified by the "path" component of the request URI.
- o unified datastore: A conceptual representation of the device running configuration. The server will hide all NETCONF datastore details for edit operations, such as the ":candidate" and ":startup" capabilities.
- o schema resource: a resource with the media type "application/yang". The YANG representation of the schema can be retrieved by the client with the GET method.
- o YANG terminal node: a YANG node representing a leaf, leaf-list, or anyxml definition.

1.4.5. Tree Diagrams

A simplified graphical representation of the data model is used in this document. The meaning of the symbols in these diagrams is as follows:

- o Brackets "[" and "]" enclose list keys.
- o Abbreviations before data node names: "rw" means configuration data (read-write) and "ro" state data (read-only).
- o Symbols after data node names: "?" means an optional node, "!" means a presence container, and "*" denotes a list and leaf-list.
- o Parentheses enclose choice and case nodes, and case nodes are also marked with a colon (":").
- o Ellipsis ("...") stands for contents of subtrees that are not shown.

2. Operations

The RESTCONF protocol uses HTTP methods to identify the CRUD operation requested for a particular resource.

The following table shows how the RESTCONF operations relate to NETCONF protocol operations:

RESTCONF	NETCONF
OPTIONS	none
HEAD	none
GET	<get-config>, <get>
POST	<edit-config> (operation="create")
PUT	<edit-config> (operation="replace")
PATCH	<edit-config> (operation="merge")
DELETE	<edit-config> (operation="delete")

Table 1: CRUD Methods in RESTCONF

The NETCONF "remove" operation attribute is not supported by the HTTP DELETE method. The resource must exist or the DELETE method will fail. The PATCH method is equivalent to a "merge" operation for a plain patch.

Access control mechanisms may be used to limit what operations can be used. In particular, RESTCONF is compatible with the NETCONF Access Control Model (NACM) [[RFC6536](#)], as there is a specific mapping between RESTCONF and NETCONF operations, defined in Table 1. The resource path needs to be converted internally by the server to the corresponding YANG instance-identifier. Using this information, the server can apply the NACM access control rules to RESTCONF messages.

The server MUST NOT allow any operation to any resources that the client is not authorized to access.

Implementation of all methods (except PATCH) are defined in [[RFC2616](#)]. This section defines the RESTCONF protocol usage for each HTTP method.

2.1. OPTIONS

The OPTIONS method is sent by the client to discover which methods are supported by the server for a specific resource. If supported, it SHOULD be implemented for all media types.

The server SHOULD implement this method, however the same information could be extracted from the YANG modules and the RESTCONF protocol specification.

If the PATCH method is supported, then the "Accept-Patch" header MUST be supported, as defined in [[RFC5789](#)].

2.2. HEAD

The HEAD method is sent by the client to retrieve just the headers that would be returned for the comparable GET method, without the response body. It is supported for all resource types, except operation resources.

The request MUST contain a request URI that contains at least the entry point component. The same query parameters supported by the GET method are supported by the HEAD method.

The access control behavior is enforced as if the method was GET instead of HEAD. The server MUST respond the same as if the method was GET instead of HEAD, except that no response body is included.

2.3. GET

The GET method is sent by the client to retrieve data and meta-data for a resource. It is supported for all resource types, except operation resources. The request MUST contain a request URI that contains at least the entry point component.

The server MUST NOT return any data resources for which the user does not have read privileges. If the user is not authorized to read the target resource, an error response containing a "403 Forbidden" or "404 Not Found" Status-Line is returned to the client.

If the user is authorized to read some but not all of the target resource, the unauthorized content is omitted from the response message body, and the authorized content is returned to the client.

Example:

The client might request the response headers for a JSON representation of the "library" resource:

```
GET /restconf/data/example-jukebox:jukebox/  
  library/artist=Foo%20Fighters/album HTTP/1.1  
Host: example.com  
Accept: application/yang.data+json,  
        application/yang.errors+json
```

The server might respond:

```

HTTP/1.1 200 OK
Date: Mon, 23 Apr 2012 17:02:40 GMT
Server: example-server
Content-Type: application/yang.data+json
Cache-Control: no-cache
Pragma: no-cache
ETag: a74eefc993a2b
Last-Modified: Mon, 23 Apr 2012 11:02:14 GMT

```

```

{
  "album" : [
    {
      "name" : "Wasting Light",
      "genre" : "example-jukebox:alternative",
      "year" : 2011
    }
  ]
}

```

2.4. POST

The POST method is sent by the client to create a data resource or invoke an operation resource. The server uses the target resource media type to determine how to process the request.

Type	Description
Datastore	Create a top-level configuration data resource
Data	Create a configuration data child resource
Operation	Invoke a protocol operation

Resource Types that Support POST

2.4.1. Create Resource Mode

If the target resource type is a datastore or data resource, then the POST is treated as a request to create a resource or child resource. The message body is expected to contain the content of a child resource to create within the parent (target resource).

The "insert" and "point" query parameters are supported by the POST method for datastore and data resource types, as specified in the YANG definition in [Section 7](#).

If the POST method succeeds, a "201 Created" Status-Line is returned and there is no response message body. A "Location" header identifying the child resource that was created MUST be present in the response in this case.

If the user is not authorized to create the target resource, an error response containing a "403 Forbidden" or "404 Not Found" Status-Line is returned to the client. All other error responses are handled according to the procedures defined in [Section 6](#).

Example:

To create a new "jukebox" resource, the client might send:

```
POST /restconf/data HTTP/1.1
Host: example.com
Content-Type: application/yang.data+json

{ "example-jukebox:jukebox" : [null] }
```

If the resource is created, the server might respond as follows:

```
HTTP/1.1 201 Created
Date: Mon, 23 Apr 2012 17:01:00 GMT
Server: example-server
Location: http://example.com/restconf/data/example-jukebox:jukebox
Last-Modified: Mon, 23 Apr 2012 17:01:00 GMT
ETag: b3a3e673be2
```

Refer to [Appendix D.2.1](#) for more resource creation examples.

[2.4.2](#). Invoke Operation Mode

If the target resource type is an operation resource, then the POST method is treated as a request to invoke that operation. The message body (if any) is processed as the operation input parameters. Refer to [Section 4.6](#) for details on operation resources.

If the POST request succeeds, a "200 OK" Status-Line is returned if there is a response message body, and a "204 No Content" Status-Line is returned if there is no response message body.

If the user is not authorized to invoke the target operation, an error response containing a "403 Forbidden" or "404 Not Found" Status-Line is returned to the client. All other error responses are handled according to the procedures defined in [Section 6](#).

Example:

In this example, the client is invoking the "play" operation defined in the "example-jukebox" YANG module.

A client might send a "play" request as follows:

```
POST /restconf/operations/example-jukebox:play HTTP/1.1
Host: example.com
Content-Type: application/yang.operation+json

{
  "example-jukebox:input" : {
    "playlist" : "Foo-One",
    "song-number" : 2
  }
}
```

The server might respond:

```
HTTP/1.1 204 No Content
Date: Mon, 23 Apr 2012 17:50:00 GMT
Server: example-server
```

2.5. PUT

The PUT method is sent by the client to create or replace the target resource.

The only target resource media type that supports PUT is the data resource. The message body is expected to contain the content used to create or replace the target resource.

The "insert" and "point" query parameters are supported by the PUT method for data resources, as specified in the YANG definition in [Section 7](#).

Consistent with [[RFC2616](#)], if the PUT request creates a new resource, a "201 Created" Status-Line is returned. If an existing resource is modified, either "200 OK" or "204 No Content" are returned.

If the user is not authorized to create or replace the target resource an error response containing a "403 Forbidden" or "404 Not Found" Status-Line is returned to the client. All other error responses are handled according to the procedures defined in [Section 6](#).

Example:

An "album" child resource defined in the "example-jukebox" YANG

module is replaced or created if it does not already exist.

To replace the "album" resource contents, the client might send as follows. Note that the request URI header line is wrapped for display purposes only:

```
PUT /restconf/data/example-jukebox:jukebox/
  library/artist=Foo%20Fighters/album=Wasting%20Light HTTP/1.1
Host: example.com
Content-Type: application/yang.data+json

{
  "example-jukebox:album" : {
    "name" : "Wasting Light",
    "genre" : "example-jukebox:alternative",
    "year" : 2011
  }
}
```

If the resource is updated, the server might respond:

```
HTTP/1.1 204 No Content
Date: Mon, 23 Apr 2012 17:04:00 GMT
Server: example-server
Last-Modified: Mon, 23 Apr 2012 17:04:00 GMT
ETag: b27480aeda4c
```

2.6. PATCH

RESTCONF uses the HTTP PATCH method defined in [[RFC5789](#)] to provide an extensible framework for resource patching mechanisms. It is optional to implement by the server. Each patch type needs a unique media type. Zero or more PATCH media types MAY be supported by the server.

A plain patch is used to create or update a child resource within the target resource. If the target resource instance does not exist, the server MUST NOT create it.

If the PATCH request succeeds, a "200 OK" Status-Line is returned if there is a message body, and "204 No Content" is returned if no response message body is sent.

If the user is not authorized to alter the target resource an error response containing a "403 Forbidden" or "404 Not Found" Status-Line is returned to the client. All other error responses are handled according to the procedures defined in [Section 6](#).

Example:

To replace just the "year" field in the "album" resource (instead of replacing the entire resource with the PUT method), the client might send a plain patch as follows. Note that the request URI header line is wrapped for display purposes only:

```
PATCH /restconf/data/example-jukebox:jukebox/
  library/artist=Foo%20Fighters/album=Wasting%20Light HTTP/1.1
Host: example.com
Content-Type: application/yang.data+json

{
  "example-jukebox:album" : {
    "genre" : "example-jukebox:rock",
    "year" : 2011
  }
}
```

If the field is updated, the server might respond:

```
HTTP/1.1 204 No Content
Date: Mon, 23 Apr 2012 17:49:30 GMT
Server: example-server
Last-Modified: Mon, 23 Apr 2012 17:49:30 GMT
ETag: b2788923da4c
```

The XML encoding for the same request might be:

```
PATCH /restconf/data/example-jukebox:jukebox/
  library/artist=Foo%20Fighters/album=Wasting%20Light HTTP/1.1
Host: example.com
If-Match: b8389233a4c
Content-Type: application/yang.data+xml

<album xmlns="http://example.com/ns/example-jukebox">
  <genre>example-jukebox:rock</genre>
  <year>2011</year>
</album>
```

[2.7.](#) DELETE

The DELETE method is used to delete the target resource. If the DELETE request succeeds, a "204 No Content" Status-Line is returned, and there is no response message body.

If the user is not authorized to delete the target resource then an

error response containing a "403 Forbidden" or "404 Not Found" Status-Line is returned to the client. All other error responses are handled according to the procedures defined in [Section 6](#).

Example:

To delete a resource such as the "album" resource, the client might send:

```
DELETE /restconf/data/example-jukebox:jukebox/
      library/artist=Foo%20Fighters/album=Wasting%20Light HTTP/1.1
Host: example.com
```

If the resource is deleted, the server might respond:

```
HTTP/1.1 204 No Content
Date: Mon, 23 Apr 2012 17:49:40 GMT
Server: example-server
```

2.8. Query Parameters

Each RESTCONF operation allows zero or more query parameters to be present in the request URI. The specific parameters that are allowed depends on the resource type, and sometimes the specific target resource used, in the request.

Name	Methods	Description
content	GET	Select config and/or non-config data resources
depth	GET	Request limited sub-tree depth in the reply content
filter	GET	Boolean notification filter for event-stream resources
insert	POST, PUT	Insertion mode for user-ordered data resources
point	POST, PUT	Insertion point for user-ordered data resources
select	GET	Request a subset of the target resource contents
start-time	GET	Replay buffer start time for event-stream resources
stop-time	GET	Replay buffer stop time for event-stream resources

RESTCONF Query Parameters

Query parameters can be given in any order. Each parameter can appear at most once in a request URI. A default value may apply if the parameter is missing.

The semantics and syntax for all query parameters are defined in the "query-parameters" YANG grouping in [Section 7](#). The YANG encoding MUST be converted to URL-encoded string for use in the request URI.

Refer to [Appendix D.3](#) for examples of query parameter usage.

3. Messages

The RESTCONF protocol uses HTTP entities for messages. A single HTTP message corresponds to a single protocol method. Most messages can perform a single task on a single resource, such as retrieving a resource or editing a resource. The exception is the PATCH method, which allows multiple datastore edits within a single message.

3.1. Request URI Structure

Resources are represented with URIs following the structure for generic URIs in [RFC3986].

A RESTCONF operation is derived from the HTTP method and the request URI, using the following conceptual fields:

`<OP> /<restconf>/<path>?<query>#<fragment>`

^	^	^	^	^
method	entry	resource	query	fragment
M	M	O	O	I

M=mandatory, O=optional, I=ignored

<text> replaced by client with real values

- o method: the HTTP method identifying the RESTCONF operation requested by the client, to act upon the target resource specified in the request URI. RESTCONF operation details are described in [Section 2](#).
- o entry: the root of the RESTCONF API configured on this HTTP server, discovered by getting the ".well-known/host-meta" resource, as described in [Section 3.2](#). All of the examples in this document assume "/restconf" as the discovered RESTCONF API root path. The URI template [RFC6570] syntax "{+restconf}" is used to refer to the entry point outside of an example.
- o resource: the path expression identifying the resource that is being accessed by the operation. If this field is not present, then the target resource is the API itself, represented by the media type "application/yang.api".

- o query: the set of parameters associated with the RESTCONF message. These have the familiar form of "name=value" pairs. There is a specific set of parameters defined, although the server MAY choose to support additional parameters not defined in this document. The contents of the any query parameter value MUST be encoded according to [\[RFC2396\], section 3.4](#). Any reserved characters MUST be encoded with escape sequences, according to [\[RFC2396\], section 2.4](#).
- o fragment: This field is not used by the RESTCONF protocol.

When new resources are created by the client, a "Location" header is returned, which identifies the path of the newly created resource. The client MUST use this exact path identifier to access the resource once it has been created.

The "target" of an operation is a resource. The "path" field in the request URI represents the target resource for the operation.

[3.2.](#) RESTCONF Path Resolution

In line the best practices defined by [\[get-off-my-lawn\]](#), RESTCONF enables deployments to specify where the RESTCONF API is located. When first connecting to a RESTCONF server, a RESTCONF client MUST determine the root of the RESTCONF API. The client discovers this by getting the `"/.well-known/host-meta"` resource ([\[RFC6415\]](#)) and using the `<Link>` element containing the "restconf" attribute :

Request

```
GET /.well-known/host-meta users HTTP/1.1
Host: example.com
Accept: application/xrd+xml
```

Response

```
HTTP/1.1 200 OK
Content-Type: application/xrd+xml
Content-Length: nnn
```

```
<XRD xmlns='http://docs.oasis-open.org/ns/xri/xrd-1.0'>
  <Link rel='restconf' href='/restconf'/>
</XRD>
```

Once discovering the RESTCONF API root, the client MUST prepend it to any subsequent request to a RESTCONF resource. For instance, using the `"/restconf"` path discovered above, the client can now determine

the operations supported by the the server:

```

Request
-----
GET /restconf/operations HTTP/1.1
Host: example.com
Accept: application/yang.api+json,
       application/yang.errors+json

Response
-----
HTTP/1.1 200 OK
Date: Mon, 23 Apr 2012 17:01:00 GMT
Server: example-server
Cache-Control: no-cache
Pragma: no-cache
Last-Modified: Sun, 22 Apr 2012 01:00:14 GMT
Content-Type: application/yang.api+json

{ "operations" : { "play" : [ null ] } }

```

3.3. Message Headers

There are several HTTP header lines utilized in RESTCONF messages. Messages are not limited to the HTTP headers listed in this section.

HTTP defines which header lines are required for particular circumstances. Refer to each operation definition section in [Section 2](#) for examples on how particular headers are used.

There are some request headers that are used within RESTCONF, usually applied to data resources. The following tables summarize the headers most relevant in RESTCONF message requests:

Name	Description
Accept	Response Content-Types that are acceptable
Content-Type	The media type of the request body
Host	The host address of the server
If-Match	Only perform the action if the entity matches ETag
If-Modified-Since	Only perform the action if modified since time
If-Unmodified-Since	Only perform the action if un-modified since time

RESTCONF Request Headers

The following tables summarize the headers most relevant in RESTCONF message responses:

Name	Description
Allow	Valid actions when 405 error returned
Cache-Control	The cache control parameters for the response
Content-Type	The media type of the response body
Date	The date and time the message was sent
ETag	An identifier for a specific version of a resource
Last-Modified	The last modified date and time of a resource
Location	The resource identifier for a newly created resource

RESTCONF Response Headers

3.4. Message Encoding

RESTCONF messages are encoded in HTTP according to [RFC 2616](#). The "utf-8" character set is used for all messages. RESTCONF message content is sent in the HTTP message body.

Content is encoded in either JSON or XML format.

XML encoding rules for data nodes are defined in [\[RFC6020\]](#). The same encoding rules are used for all XML content.

JSON encoding rules are defined in [\[I-D.lhotka-netmod-json\]](#). This encoding is valid JSON, but also has special encoding rules to identify module namespaces and provide consistent type processing of YANG data.

Request input content encoding format is identified with the Content-Type header. This field MUST be present if a message body is sent by the client.

Response output content encoding format is identified with the Accept header in the request, or if is not specified, the request input encoding format is used. If there was no request input, then the default output encoding is XML. File extensions encoded in the request are not used to identify format encoding.

[3.5.](#) RESTCONF Meta-Data

The RESTCONF protocol needs to retrieve the same meta-data that is used in the NETCONF protocol. Information about default leafs, last-modified timestamps, etc. are commonly used to annotate representations of the datastore contents. This meta-data is not defined in the YANG schema because it applies to the datastore, and is common across all data nodes.

This information is encoded as attributes in XML. JSON encoding of meta-data is defined in [[I-D.lhotka-netmod-json](#)].

[3.6.](#) Return Status

Each message represents some sort of resource access. An HTTP "Status-Line" header line is returned for each request. If a 4xx or 5xx range status code is returned in the Status-Line, then the error information will be returned in the response, according to the format defined in [Section 6.1](#).

[3.7.](#) Message Caching

Since the datastore contents change at unpredictable times, responses from a RESTCONF server generally SHOULD NOT be cached.

The server SHOULD include a "Cache-Control" header in every response that specifies whether the response should be cached. A "Pragma" header specifying "no-cache" MAY also be sent in case the "Cache-Control" header is not supported.

Instead of using HTTP caching, the client SHOULD track the "ETag" and/or "Last-Modified" headers returned by the server for the datastore resource (or data resource if the server supports it). A retrieval request for a resource can include the "If-None-Match" and/or "If-Modified-Since" headers, which will cause the server to return a "304 Not Modified" Status-Line if the resource has not changed. The client MAY use the HEAD method to retrieve just the message headers, which SHOULD include the "ETag" and "Last-Modified" headers, if this meta-data is maintained for the target resource.

4. Resources

The RESTCONF protocol operates on a hierarchy of resources, starting with the top-level API resource itself. Each resource represents a manageable component within the device.

A resource can be considered a collection of conceptual data and the set of allowed methods on that data. It can contain nested child resources. The child resource types and methods allowed on them are data-model specific.

A resource has its own media type identifier, represented by the "Content-Type" header in the HTTP response message. A resource can contain zero or more nested resources. A resource can be created and deleted independently of its parent resource, as long as the parent resource exists.

All RESTCONF resources are defined in this document except datastore contents, protocol operations, and notification events. The syntax and semantics for these resource types are defined in YANG modules.

The RESTCONF resources are accessed via a set of URIs defined in this document. The set of YANG modules supported by the server will determine the data model specific operations, top-level data node resources, and notification event messages supported by the server.

The resources used in the RESTCONF protocol are identified by the "path" component in the request URI. Each operation is performed on a target resource.

4.1. RESTCONF Resource Types

The RESTCONF protocol defines a set of application specific media types to identify each of the available resource types. The following resource types are defined in RESTCONF:

Resource	Media Type
API	application/yang.api
Datastore	application/yang.datastore
Data	application/yang.data
Errors	application/yang.errors
Operation	application/yang.operation
Schema	application/yang
Stream	application/yang.stream

RESTCONF Media Types

4.2. Resource Discovery

A client SHOULD start by retrieving the top-level API resource, using the entry point URI defined in [Section 3.2](#).

The RESTCONF protocol does not include a resource discovery mechanism. Instead, the definitions within the YANG modules advertised by the server are used to construct a predictable operation or data resource identifier.

The "depth" query parameter can be used to control how many descendant levels should be included when retrieving child resources. This parameter can be used with the GET method to discover child resources within a particular resource.

4.3. API Resource

The API resource contains the state and access points for the RESTCONF features. It is the top-level resource and has the media type "application/yang.api+xml" or "application/yang.api+json".

YANG Tree Diagram for "application/yang.api" Resource Type:

```

+--rw restconf
  +--rw data
  +--rw modules
    | +--rw module* [name revision]
    |   +--rw name          yang:yang-identifier
    |   +--rw revision      union
    |   +--rw schema?       empty
    |   +--rw namespace     inet:uri
    |   +--rw feature*      yang:yang-identifier
    |   +--rw deviation*    yang:yang-identifier
    |   +--rw submodule* [name revision]
    |     +--rw name          yang:yang-identifier
    |     +--rw revision      union
    |     +--rw schema?       empty
  +--rw operations
  +--rw streams
    +--rw stream* [name]
      +--rw name              string
      +--rw description?     string
      +--rw replay-support?   boolean
      +--rw replay-log-creation-time? yang:date-and-time
      +--rw events?           empty

```

The "restconf" container definition in the "ietf-restconf" module defined in [Section 7](#) is used to specify the structure and syntax of the conceptual child resources within the API resource.

This resource has the following child resources:

Child Resource	Description
data	Contains all data resources
modules	YANG module information
operations	Data-model specific operations
streams	Notification event streams

RESTCONF Resources

4.3.1. {+restconf}/data

This mandatory resource represents the combined configuration and operational data resources that can be accessed by a client. It cannot be created or deleted by the client. The datastore resource type is defined in [Section 4.4](#).

Example:

This example request by the client would retrieve only the non-configuration data nodes that exist within the "library" resource, using the "content" query parameter.

```
GET /restconf/data/example-jukebox:jukebox/library
    ?content=nonconfig HTTP/1.1
Host: example.com
Accept: application/yang.data+json,
        application/yang.errors+json
```

The server might respond:

```
HTTP/1.1 200 OK
Date: Mon, 23 Apr 2012 17:01:30 GMT
Server: example-server
Cache-Control: no-cache
Pragma: no-cache
Content-Type: application/yang.data+json
```

```
{
  "example-jukebox:library" : {
    "artist-count" : 42,
    "album-count" : 59,
    "song-count" : 374
  }
}
```

[4.3.2.](#) `{+restconf}/modules`

This mandatory resource contains the identifiers for the YANG data model modules supported by the server.

The server **MUST** maintain a last-modified timestamp for this resource, and return the "Last-Modified" header when this resource is retrieved with the GET or HEAD methods.

The server **SHOULD** maintain an entity-tag for this resource, and return the "ETag" header when this resource is retrieved with the GET or HEAD methods.

[4.3.2.1.](#) `{+restconf}/modules/module`

This mandatory resource contains one list entry for each YANG data model module supported by the server. There **MUST** be an instance of this resource for every YANG module that is accessible via an operation resource or a data resource.

The contents of the "module" resource are defined in the "module" YANG list statement in [Section 7](#).

The server **MAY** maintain a last-modified timestamp for each instance of this resource, and return the "Last-Modified" header when this resource is retrieved with the GET or HEAD methods. If not supported then the timestamp for the parent "modules" resource **MAY** be used instead.

The server **MAY** maintain an entity-tag for each instance of this resource, and return the "ETag" header when this resource is retrieved with the GET or HEAD methods. If not supported then the timestamp for the parent "modules" resource **MAY** be used instead.

4.3.3. `{+restconf}/operations`

This optional resource is a container that provides access to the data-model specific protocol operations supported by the server. The server MAY omit this resource if no data-model specific operations are advertised.

Any data-model specific operations defined in the YANG modules advertised by the server MAY be available as child nodes of this resource.

Operation resources are defined in [Section 4.6](#).

4.3.4. `{+restconf}/streams`

This optional resource is a container that provides access to the notification event streams supported by the server. The server MAY omit this resource if no notification event streams are supported. The media type for this resource is "application/yang.api".

The server will populate this container with a stream list entry for each stream type it supports. Each stream contains a leaf called "events" which represents an event stream resource. The media type for this resource is "application/yang.stream".

Stream resources are defined in [Section 4.8](#). Notifications are defined in [Section 5](#).

4.4. Datastore Resource

The "`{+restconf}/data`" subtree represents the datastore resource type, which is a collection of configuration and operational data nodes.

A "unified datastore" interface is used to simplify resource editing for the client. The RESTCONF unified datastore is a conceptual interface to the native configuration datastores that are present on the device.

The underlying NETCONF datastores (i.e., candidate, running, startup) can be used to implement the unified datastore, but the server design is not limited to the exact datastore procedures defined in NETCONF.

The "candidate" and "startup" datastores are not visible in the RESTCONF protocol. Transaction management and configuration persistence are handled by the server and not controlled by the client.

A datastore resource can only be written directly with the PATCH method. Only the configuration data resources within the datastore resource can be edited directly with all methods.

Each RESTCONF edit of a datastore resource is saved to non-volatile storage in an implementation-specific matter by the server. There is no guarantee that configuration changes are saved immediately, or that the saved configuration is always a mirror of the running configuration.

4.4.1. Edit Collision Detection

Two "edit collision detection" mechanisms are provided in RESTCONF, for datastore and data resources.

4.4.1.1. Timestamp

The last change time is maintained and the "Last-Modified" and "Date" headers are returned in the response for a retrieval request. The "If-Unmodified-Since" header can be used in edit operation requests to cause the server to reject the request if the resource has been modified since the specified timestamp.

The server MUST maintain a last-modified timestamp for this resource, and return the "Last-Modified" header when this resource is retrieved with the GET or HEAD methods. Only changes to configuration data resources within the datastore affect this timestamp.

4.4.1.2. Entity tag

A unique opaque string is maintained and the "ETag" header is returned in the response for a retrieval request. The "If-Match" header can be used in edit operation requests to cause the server to reject the request if the resource entity tag does not match the specified value.

The server MUST maintain a resource entity tag for this resource, and return the "ETag" header when this resource is retrieved with the GET or HEAD methods. The resource entity tag MUST be changed to a new previously unused value if changes to any configuration data resources within the datastore are made.

4.5. Data Resource

A data resource represents a YANG data node that is a descendant node of a datastore resource.

For configuration data resources, the server MAY maintain a last-

modified timestamp for the resource, and return the "Last-Modified" header when it is retrieved with the GET or HEAD methods. If maintained, the resource timestamp MUST be set to the current time whenever the resource or any configuration resource within the resource is altered.

For configuration data resources, the server MAY maintain a resource entity tag for the resource, and return the "ETag" header when it is retrieved as the target resource with the GET or HEAD methods. If maintained, the resource entity tag MUST be updated whenever the resource or any configuration resource within the resource is altered.

A data resource can be retrieved with the GET method. Data resources are accessed via the "{+restconf}/data" entry point. This sub-tree is used to retrieve and edit data resources.

A configuration data resource can be altered by the client with some or all of the edit operations, depending on the target resource and the specific operation. Refer to [Section 2](#) for more details on edit operations.

The resource definition version for a data resource is identified by the revision date of the YANG module containing the YANG definition for the data resource, specified in the "{+restconf}/modules" sub-tree.

[4.5.1. Encoding YANG Instance Identifiers in the Request URI](#)

In YANG, data nodes are named with an absolute XPath expression, defined in [[XPath](#)], starting from the document root to the target resource. In RESTCONF, URL encoded Location header expressions are used instead.

The YANG "instance-identifier" (i-i) data type is represented in RESTCONF with the path expression format defined in this section.

```

+-----+-----+
| Name   | Comments |
+-----+-----+
| point  | Insertion point is always a full i-i |
| path   | Request URI path is a full or partial i-i |
+-----+-----+

```

RESTCONF instance-identifier Type Conversion

The "path" component of the request URI contains the absolute path expression that identifies the target resource.

A predictable location for a data resource is important, since applications will code to the YANG data model module, which uses static naming and defines an absolute path location for all data nodes.

A RESTCONF data resource identifier is not an XPath expression. It is encoded from left to right, starting with the top-level data node, according to the "api-path" rule in [Section 4.5.1.1](#). The node name of each ancestor of the target resource node is encoded in order, ending with the node name for the target resource.

If a data node in the path expression is a YANG list node, then the key values for the list (if any) MUST be encoded according to the following rules.

- o The key leaf values for a data resource representing a YANG list MUST be encoded using one path segment [[RFC3986](#)].
- o If there is only one key leaf value, the path segment is constructed by having the list name followed by an "=" followed by the single key leaf value.
- o If there are multiple key leaf values, the value of each leaf identified in the "key" statement is encoded in the order specified in the YANG "key" statement, with a comma separating them.
- o All the components in the "key" statement MUST be encoded. Partial instance identifiers are not supported.
- o Quoted strings are supported in the key leaf values. Quoted strings MUST be used to express empty strings. (example: list=foo, '', baz).
- o The "list-instance" ABNF rule defined in [Section 4.5.1.1](#) represents the syntax of a list instance identifier.
- o Resource URI values returned in Location headers for data resources MUST identify the module name, even if there are no conflicting local names when the resource is created. This ensures the correct resource will be identified even if the server loads a new module that the old client does not know about.

Examples:

```

container top {
  list list1 {
    key "key1 key2 key3";
    ...
  }
  list list2 {
    key "key4 key5";
    ...
    leaf X { type string; }
  }
}

```

For the above YANG definition, URI with key leaf values will be encoded as follows (line wrapped for display purposes only):

```

/restconf/data/top/list1=key1val,key2val,key3val3/
  list2=key4val,key5val/X

```

[4.5.1.1.](#) ABNF For Data Resource Identifiers

The "api-path" ABNF syntax is used to construct RESTCONF path identifiers:

```

api-path = "/" |
          ("/" api-identifier
           0*("/" (api-identifier | list-instance )))

api-identifier = [module-name ":" ] identifier

module-name = identifier

list-instance = api-identifier "=" key-value ["," key-value]*

key-value = string

string = <a quoted or unquoted or empty string>

; ; An identifier MUST NOT start with
; ; (('X'|'x') ('M'|'m') ('L'|'l'))
identifier = (ALPHA / "_")
            *(ALPHA / DIGIT / "_" / "-" / ".")

```

[4.5.2.](#) Defaults Handling

NETCONF has a rather complex model for handling default values for leafs. RESTCONF attempts to avoid this complexity by restricting the operations that can be applied to a resource. Applications that require full control of defaults might consider NETCONF instead of RESTCONF.

If the target of a GET method is a data node that represents a leaf that has a default value, and the leaf has not been given a value yet, the server MUST return the default value that is in use by the server.

If the target of a GET method is a data node that represents a container or list that has any child resources with default values, for the child resources that have not been given value yet, the server MAY return the default values that are in use by the server.

4.6. Operation Resource

An operation resource represents an protocol operation defined with the YANG "rpc" statement.

All operation resources share the same module namespace as any top-level data resources, so the name of an operation resource cannot conflict with the name of a top-level data resource defined within the same module.

If 2 different YANG modules define the same "rpc" identifier, then the module name MUST be used in the request URI. For example, if "module-A" and "module-B" both defined a "reset" operation, then invoking the operation from "module-A" would be requested as follows:

```
POST /restconf/operations/module-A:reset HTTP/1.1
Server example.com
```

Any usage of an operation resource from the same module, with the same name, refers to the same "rpc" statement definition. This behavior can be used to design protocol operations that perform the same general function on different resource types.

If the "rpc" statement has an "input" section, then a message body MAY be sent by the client in the request, otherwise the request message MUST NOT include a message body. If the "rpc" statement has an "output" section, then a message body MAY be sent by the server in the response. Otherwise the server MUST NOT include a message body in the response message, and MUST send a "204 No Content" Status-Line instead.

4.6.1. Encoding Operation Input Parameters

If the "rpc" statement has an "input" section, then the "input" node is provided in the message body, corresponding to the YANG data definition statements within the "input" section.

Example:

The following YANG definition is used for the examples in this section.

```
rpc reboot {
  input {
    leaf delay {
      units seconds;
      type uint32;
      default 0;
    }
    leaf message { type string; }
    leaf language { type string; }
  }
}
```

The client might send the following POST request message:

```
POST /restconf/operations/example-ops:reboot HTTP/1.1
Host: example.com
Content-Type: application/yang.operation+json
```

```
{
  "example-ops:input" : {
    "delay" : 600,
    "message" : "Going down for system maintenance",
    "language" : "en-US"
  }
}
```

The server might respond:

```
HTTP/1.1 204 No Content
Date: Mon, 25 Apr 2012 11:01:00 GMT
Server: example-server
```

4.6.2. Encoding Operation Output Parameters

If the "rpc" statement has an "output" section, then the "output" node is provided in the message body, corresponding to the YANG data definition statements within the "output" section.

Example:

The following YANG definition is used for the examples in this section.

```
rpc get-reboot-info {
  output {
    leaf reboot-time {
      units seconds;
      type uint32;
    }
    leaf message { type string; }
    leaf language { type string; }
  }
}
```

The client might send the following POST request message:

```
POST /restconf/operations/example-ops:get-reboot-info HTTP/1.1
Host: example.com
Accept: application/yang.operation+json,
        application/yang.errors+json
```

The server might respond:

```
HTTP/1.1 200 OK
Date: Mon, 25 Apr 2012 11:10:30 GMT
Server: example-server
Content-Type: application/yang.operation+json
```

```
{
  "example-ops:output" : {
    "reboot-time" : 30,
    "message" : "Going down for system maintenance",
    "language" : "en-US"
  }
}
```

[4.7.](#) Schema Resource

If the server supports the "schema" leaf within the API then the client can retrieve the YANG schema text for the associated YANG module or submodule, using the GET method.

The client might send the following GET request message:

```
GET /restconf/modules/module=example-jukebox,2014-07-03/schema
HTTP/1.1
Host: example.com
Accept: application/yang,
        application/yang.errors+json
```

The server might respond:

```
HTTP/1.1 200 OK
Date: Mon, 25 Apr 2012 11:10:30 GMT
Server: example-server
Content-Type: application/yang

module example-jukebox {

    namespace "http://example.com/ns/example-jukebox";
    prefix "jbox";

    // rest of YANG module content deleted...
}
```

4.8. Stream Resource

A "stream" resource represents a source for system generated event notifications. Each stream is created and modified by the server only. A client can retrieve a stream resource or initiate a long-poll server sent event stream, using the procedure specified in [Section 5.3](#).

A notification stream functions according to the NETCONF Notifications specification [[RFC5277](#)]. The "ietf-restconf" YANG module contains the "stream" list ("{"restconf}/streams/stream") which specifies the syntax and semantics of a stream resource.

4.9. Errors Resource

An "errors" resource is a collection of error information that is sent as the message body in a server response message, if an error occurs while processing a request message.

The "ietf-restconf" YANG module contains the "errors" grouping which specifies the syntax and semantics of an errors resource. RESTCONF error handling behavior is defined in [Section 6](#).

5. Notifications

The RESTCONF protocol supports YANG-defined event notifications. The solution preserves aspects of NETCONF Event Notifications [[RFC5277](#)] while utilizing the Server-Sent Events [[wd-eventsource](#)] transport strategy.

5.1. Server Support

A RESTCONF server is not required to support RESTCONF notifications. Clients may determine if a server supports RESTCONF notifications by using the HTTP operation OPTIONS, HEAD, or GET on the "{+restconf}/streams" resource described below. The server does not support RESTCONF notifications if an HTTP error code is returned (e.g., 404 Not Found).

5.2. Event Streams

A RESTCONF server that supports notifications will populate a stream resource for each notification delivery service access point. A RESTCONF client can retrieve the list of supported event streams from a RESTCONF server using the GET operation on the "{+restconf}/streams" resource.

The "{+restconf}/streams" container definition in the "ietf-restconf" module defined in [Section 7](#) is used to specify the structure and syntax of the conceptual child resources within the "streams" resource.

For example:

The client might send the following request:

```
GET /restconf/streams HTTP/1.1
Host: example.com
Accept: application/yang.api+xml,
       application/yang.errors+xml
```

The server might send the following response:

```
HTTP/1.1 200 OK
Content-Type: application/yang.api+xml
```

```
<streams xmlns="urn:ietf:params:xml:ns:yang:ietf-restconf">
  <stream>
    <name>NETCONF</name>
    <description>default NETCONF event stream
    </description>
    <replay-support>true</replay-support>
    <replay-log-creation-time>
      2007-07-08T00:00:00Z

```

5.3. Subscribing to Receive Notifications

RESTCONF clients can subscribe to receive notifications by sending an HTTP GET request for the "{+restconf}/streams/stream/<stream-name>" resource, with the "Accept" type "text/event-stream". The server will treat the connection as an event stream, using the Server Sent Events [[wd-eventsource](#)] transport strategy.

The server MAY support query parameters for a GET method on this resource. These parameters are specific to each notification stream.

For example:

```
GET /restconf/streams/stream=NETCONF/events HTTP/1.1
Host: example.com
Accept: text/event-stream
Cache-Control: no-cache
Connection: keep-alive
```

A RESTCONF client MAY request the server compress the events using the HTTP header field "Accept-Encoding". For instance:

```
GET /restconf/streams/stream=NETCONF/events HTTP/1.1
Host: example.com
Accept: text/event-stream
Cache-Control: no-cache
Connection: keep-alive
Accept-Encoding: gzip, deflate
```

5.3.1. NETCONF Event Stream

The server SHOULD support the "NETCONF" notification stream defined in [RFC5277]. For this stream, RESTCONF notification subscription requests MAY specify parameters indicating the events it wishes to receive.

Name	Description
start-time	replay event start time
stop-time	replay event stop time
filter	boolean content filter

NETCONF Stream Query Parameters

The semantics and syntax for these query parameters are defined in the "query-parameters" YANG grouping in [Section 7](#). The YANG encoding MUST be converted to URL-encoded string for use in the request URI.

Refer to [Appendix D.3.3](#) for filter parameter examples.

5.4. Receiving Event Notifications

RESTCONF notifications are encoded according to the definition of the event stream. The NETCONF stream defined in [RFC5277] is encoded in XML format.

The structure of the event data is based on the "notification" element definition in [section 4 of \[RFC5277\]](#). It MUST conform to the "notification" YANG container definition in [Section 7](#).

An example SSE notification encoded using XML:

```
data: <notification
data:   xmlns="urn:ietf:params:xml:ns:yang:ietf-restconf">
data:   <event-time>2013-12-21T00:01:00Z</event-time>
data:   <event xmlns="http://example.com/event/1.0">
data:     <eventClass>fault</eventClass>
data:     <reportingEntity>
data:       <card>Ethernet0</card>
data:     </reportingEntity>
data:     <severity>major</severity>
data:   </event>
data: </notification>
```

Since XML is not whitespace sensitive, the above message can be encoded onto a single line.

For example: ('\ ' line wrapping added for formatting only)

```
data: <notification xmlns="urn:ietf:params:xml:ns:yang:ietf-rest\
conf"><event-time>2013-12-21T00:01:00Z</event-time><event xmlns="\
http://example.com/event/1.0"><eventClass>fault</eventClass><repo\
rtingEntity><card>Ethernet0</card></reportingEntity><severity>maj\
or</severity></event></notification>
```

The SSE specifications supports the following additional fields: event, id and retry. A RESTCONF server MAY send the "retry" field and, if it does, RESTCONF clients SHOULD use it. A RESTCONF server SHOULD NOT send the "event" or "id" fields, as there are no meaningful values that could be used for them that would not be redundant to the contents of the notification itself. RESTCONF servers that do not send the "id" field also do not need to support the HTTP header "Last-Event-Id". RESTCONF servers that do send the "id" field MUST still support the "startTime" query parameter as the preferred means for a client to specify where to restart the event stream.

6. Error Reporting

HTTP Status-Lines are used to report success or failure for RESTCONF operations. The <rpc-error> element returned in NETCONF error responses contains some useful information. This error information is adapted for use in RESTCONF, and error information is returned for "4xx" class of status codes.

The following table summarizes the return status codes used specifically by RESTCONF operations:

Status-Line	Description
100 Continue	POST accepted, 201 should follow
200 OK	Success with response body
201 Created	POST to create a resource success
202 Accepted	POST to create a resource accepted
204 No Content	Success without response body
304 Not Modified	Conditional operation not done
400 Bad Request	Invalid request message
403 Forbidden	Access to resource denied
404 Not Found	Resource target or resource node not found
405 Method Not Allowed	Method not allowed for target resource
409 Conflict	Resource or lock in use
412 Precondition Failed	Conditional method is false
413 Request Entity Too Large	too-big error
414 Request-URI Too Large	too-big error
415 Unsupported Media Type	non RESTCONF media type
500 Internal Server Error	operation-failed
501 Not Implemented	unknown-operation
503 Service Unavailable	Recoverable server error

HTTP Status Codes used in RESTCONF

Since an operation resource is defined with a YANG "rpc" statement, a mapping between the NETCONF <error-tag> value and the HTTP status code is needed. The specific error condition and response code to use are data-model specific and might be contained in the YANG "description" statement for the "rpc" statement.

<error-tag>	status code
in-use	409
invalid-value	400
too-big	413
missing-attribute	400
bad-attribute	400
unknown-attribute	400
bad-element	400
unknown-element	400
unknown-namespace	400
access-denied	403
lock-denied	409
resource-denied	409
rollback-failed	500
data-exists	409
data-missing	409
operation-not-supported	501
operation-failed	500
partial-operation	500
malformed-message	400

Mapping from error-tag to status code

6.1. Error Response Message

When an error occurs for a request message on a data resource or an operation resource, and a "4xx" class of status codes (except for status code "403 Forbidden"), then the server SHOULD send a response body containing the information described by the "errors" container definition within the YANG module [Section 7](#). The Content-Type of this response message MUST be application/yang.errors.

YANG Tree Diagram for <errors> Data:

```

+--ro errors
  +--ro error
    +--ro error-type      enumeration
    +--ro error-tag      string
    +--ro error-app-tag? string
    +--ro (error-node)?
      | +--:(error-path)
      | | +--ro error-path?      instance-identifier
      | +--:(error-urlpath)
      |   +--ro error-urlpath?  data-resource-identifier
    +--ro error-message?  string
  
```

`+--ro error-info`

The semantics and syntax for RESTCONF error messages are defined in the "errors" YANG grouping in [Section 7](#).

Examples:

The following example shows an error returned for an "lock-denied" error on a datastore resource.

```
POST /restconf/operations/example-ops:lock-datastore HTTP/1.1
Host: example.com
```

The server might respond:

```
HTTP/1.1 409 Conflict
Date: Mon, 23 Apr 2012 17:11:00 GMT
Server: example-server
Content-Type: application/yang.errors+json
```

```
{
  "ietf-restconf:errors": {
    "error": {
      "error-type": "protocol",
      "error-tag": "lock-denied",
      "error-message": "Lock failed, lock already held"
    }
  }
}
```

The following example shows an error returned for a "data-exists" error on a data resource. The "jukebox" resource already exists so it cannot be created.

The client might send:

```
POST /restconf/data/example-jukebox:jukebox HTTP/1.1
Host: example.com
```

The server might respond:

HTTP/1.1 409 Conflict
Date: Mon, 23 Apr 2012 17:11:00 GMT
Server: example-server
Content-Type: application/yang.errors+json

```
{
  "ietf-restconf:errors": {
    "error": {
      "error-type": "protocol",
      "error-tag": "data-exists",
      "error-uripath": "http://example.com/restconf/data/
        example-jukebox:jukebox",
      "error-message":
        "Data already exists, cannot create new resource"
    }
  }
}
```

7. RESTCONF module

The "ietf-restconf" module defines conceptual definitions within groupings, which are not meant to be implemented as datastore contents by a server.

The "ietf-yang-types" and "ietf-inet-types" modules from [[RFC6991](#)] are used by this module for some type definitions.

RFC Ed.: update the date below with the date of RFC publication and remove this note.

revision 2014-07-03 {
  description
    "Initial revision.";
  reference
    "RFC XXXX: RESTCONF Protocol.";
}

typedef data-resource-identifier {
  type string {
    length "1 .. max";
  }
  description
    "Contains a Data Resource Identifier formatted string
    to identify a specific data resource instance.
    The document root for all data resources is a
    datastore resource container. Each top-level YANG
    data nodes supported by the server will be represented
```

as a child node of the document root.

The canonical representation of a data resource identifier includes the full server specification that is returned in the Location header when a new data resource is created with the POST method.

The abbreviated representation does not contain any server location identification. Instead the identifier will start with the '/' character to represent the datastore document root for the data resource instance.

The server MUST accept either representation and SHOULD return the canonical representation in any response message.";

    }
  }
  default last;
  description
    "The 'insert' parameter is used to specify how a
    resource should be inserted within a user-ordered list.

    This parameter is only supported for the POST and PUT
    methods. It is also only supported if the target
    resource is a data resource, and that data represents
    a YANG list or leaf-list that is ordered by the user.

    If the values 'before' or 'after' are used,
    then a 'point' query parameter for the insertion
    parameter MUST also be present, or a 400 Bad Request
    error is returned.";
}
```

```
leaf point {
  type data-resource-identifier;
  description
    "The 'point' parameter is used to specify the
    insertion point for a data resource that is being
```

created or moved within a user ordered list or leaf-list.

This parameter is only supported for the POST and PUT methods. It is also only supported if the target resource is a data resource, and that data represents a YANG list or leaf-list that is ordered by the user.

If the 'insert' query parameter is not present, or has a value other than 'before' or 'after', then a 400 Bad Request error is returned.

This parameter contains the instance identifier of the resource to be used as the insertion point for a POST or PUT method.";

}

leaf select {

```
  type string {
    length "1 .. max";
  }
```

description

"The 'select' query parameter is used to optionally identify data nodes within the target resource to be retrieved in a GET method. The client can use this parameter to retrieve a subset of all nodes in a resource.

A value of the 'select' query parameter matches the following rule:

```
select-expr = path '(' select-expr / '*' ')' /
              path ';' select-expr /
              path
path = api-identifier [ '/' path ]
```

'api-identifier' is defined in [section 5.3.1.1](#).

';' is used to select multiple nodes. For example, to retrieve only the 'genre' and 'year' of an album, use: 'select=genre;year'.

Parentheses are used to specify sub-selectors of a node. For example, to retrieve only the 'label' and 'catalogue-number' of an album, use: 'select=admin(label;catalogue-number)'.

'/' is used in a path to retrieve a child node of a node. For example, to retrieve only the 'label' of an album, use: 'select=admin/label'.

This parameter is only allowed for GET methods on api, datastore, and data resources. A 400 Bad Request error is returned if used for other methods or resource types.";

reference

```

<CODE ENDS>

8. IANA Considerations

8.1. The "restconf" Relation Type

This specification registers the "restconf" relation type in the Link Relation Type Registry defined by [[RFC5988](#)]:

Relation Name: restconf

Description: Identifies the root of RESTCONF API as configured on this HTTP server. The "restconf" relation defines the root of the API defined in RFCXXXX. Subsequent revisions of RESTCONF will use alternate relation values to support protocol versioning.

Reference: RFC XXXX

8.2. YANG Module Registry

This document registers one URI in the IETF XML registry [[RFC3688](#)]. Following the format in [RFC 3688](#), the following registration is requested to be made.

URI: urn:ietf:params:xml:ns:yang:ietf-restconf
Registrant Contact: The NETMOD WG of the IETF.
XML: N/A, the requested URI is an XML namespace.

This document registers one YANG module in the YANG Module Names registry [[RFC6020](#)].

name: ietf-restconf
namespace: urn:ietf:params:xml:ns:yang:ietf-restconf
prefix: rc
// RFC Ed.: replace XXXX with RFC number and remove this note
reference: RFC XXXX

8.3. application/yang Media Sub Types

The parent MIME media type for RESTCONF resources is application/yang, which is defined in [[RFC6020](#)]. This document defines the following sub-types for this media type.

- api
- data
- datastore
- errors
- operation
- stream

Type name: application

Subtype name: yang.xxx

Required parameters: TBD

Optional parameters: TBD

Encoding considerations: TBD

Security considerations: TBD

Interoperability considerations: TBD

// RFC Ed.: replace XXXX with RFC number and remove this note

Published specification: RFC XXXX

9. Security Considerations

This section provides security considerations for the resources defined by the RESTCONF protocol. Security considerations for HTTPS are defined in [\[RFC2818\]](#). Security considerations for the content manipulated by RESTCONF can be found in the documents defining data models.

This document does not specify an authentication scheme, but it does require that an authenticated NETCONF username be associated with each HTTP request. The authentication scheme MAY be implemented in the underlying transport layer (e.g., client certificates) or within the HTTP layer (e.g., Basic Auth, OAuth, etc.). RESTCONF does not itself define an authentication mechanism, authentication MUST occur in a lower layer. Implementors SHOULD provide a comprehensive authorization scheme with RESTCONF and ensure that the resulting NETCONF username is made available to the RESTCONF server.

Authorization of individual user access to operations and data MAY be configured via NETCONF Access Control Model (NACM) [\[RFC6536\]](#), as specified in [Section 2](#). Other authorization models MAY be used, but are outside of the scope of this document.

Configuration information is by its very nature sensitive. Its transmission in the clear and without integrity checking leaves devices open to classic eavesdropping and false data injection attacks. Configuration information often contains passwords, user names, service descriptions, and topological information, all of which are sensitive. Because of this, this protocol SHOULD be implemented carefully with adequate attention to all manner of attack one might expect to experience with other management interfaces.

Different environments may well allow different rights prior to and then after authentication. When an operation is not properly authorized, the RESTCONF server MUST return HTTP error status code 401 Unauthorized. Note that authorization information can be exchanged in the form of configuration information, which is all the more reason to ensure the security of the connection.

[Appendix A](#). Change Log

-- RFC Ed.: remove this section before publication.

[A.1](#). 00 - 01

- o fixed content=nonconfig example (non-config was incorrect)
- o closed open issue 'message-id'. There is no need for a message-id field, and [RFC 2392](#) does not apply.
- o closed open issue 'server support verification'. The headers used by RESTCONF are widely supported.
- o removed encoding rules from section on RESTCONF Meta-Data. This is now defined in [[I-D.lhotka-netmod-json](#)].
- o added media type application/yang.errors to map to errors YANG grouping. Updated error examples to use new media type.
- o closed open issue 'additional datastores'. Support may be added in the future to identify new datastores.
- o closed open issue 'PATCH media type discovery'. The section on PATCH has an added sentence on the Accept-Patch header.
- o closed open issue 'YANG to resource mapping'. Current mapping of all data nodes to resources will be used in order to allow mandatory DELETE support. The PATCH operation is optional, as well as the YANG Patch media type.
- o closed open issue '_self links for HATEOAS support'. It was decided that they are redundant because they can be derived from the YANG module for the specific data.
- o added explanatory text for the 'select' parameter.
- o added RESTCONF Path Resolution section for discovering the root of the RESTCONF API using the /.well-known/host-meta.
- o added an "error" media type to for structured error messages
- o added Secure Transport section requiring TLS
- o added Security Considerations section
- o removed all references to "REST-like"

[A.2.](#) bierman:restconf-04 to ietf:restconf-00

- o updated open issues section

Appendix B. Open Issues

-- RFC Ed.: remove this section before publication.

B.1. select parameter

- o What syntax should be used for the "select" query parameter? The current choices are "XPath" and "path-expr". Perhaps an additional parameter to identify the select string format is needed to allow extensibility?

Status: solution proposal added by Martin.

B.2. netconf-state monitoring support

- o Should long-term RESTCONF operations (i.e. SSE long-poll) be considered sessions with regards to NETCONF monitoring "session" list? If so, what text is needed in RESTCONF draft to standardize the RESTCONF session entries?

Status: closed-update-pending

Resolution:

A new data structure to monitor streams can be added to the netconf-state sub-tree. The session-id in this new data structure is not restricted to the NETCONF-only rules for the sessions sub-tree.

B.3. secure transport

- o Details to support secure operation over TLS are needed

Status: closed

- o Security considerations need to be written

Status: closed

- o Can call-home for RESTCONF be supported

Status: open

B.4. Encoding of key leafs in resource URIs

- o The use of a forward slash '/' as the delimiter between key values in a target resource URI is not desirable. Only 1 segment per YANG data node layer should be used.

Status: open

Proposals:

Example: list foo, int8 keys X and Y

Old:

```
/restconf/data/foo/19/22/foo-leaf
```

New:

```
/restconf/data/foo=19,22/foo-leaf
```

Or:

```
/restconf/data/foo/19,22/foo-leaf
```

[B.5.](#) get-bulk query parameters

- o New query parameters (e.g., offset, limit) are needed to retrieve a limited number of list instances.

Status: solution proposal pending

Resolution: This bulk retrieval mechanism will be added.

[B.6.](#) defaults handling

- o The client does not really know what sort of defaults the server will return in GET replies. Should the with-defaults query parameter be added to RESTCONF? If so, should it be mandatory-to-implement?

Status: open

[B.7.](#) protocol capability URIs

- o The client does not know what vendor extensions (if any) are implemented by the server. Should the server provide a read-only container of capability URIs to identify protocol extensions? The NETMOD WG may also want to extend the protocol in the future without updating the core RESTCONF RFC.

Status: open

B.8. target resource list keys required for GET

- o Should the client be able to GET all or a subset of all list instances by issuing a GET without any list keys for the target resource list?

GET /restconf/data/interfaces/interface

- o Should a "collection" resource be required in order for such a request to be considered valid by the server.

Status: open

[Appendix C.](#) Example YANG Module

The example YANG module used in this document represents a simple media jukebox interface.

YANG Tree Diagram for "example-jukebox" Module

```

+--rw jukebox?
  +--rw library
    | +--rw artist [name]
    | | +--rw name      string
    | | +--rw album [name]

}
```

[Appendix D](#). RESTCONF Message Examples

The examples within this document use the normative YANG module defined in [Section 7](#) and the non-normative example YANG module defined in [Appendix C.1](#).

This section shows some typical RESTCONF message exchanges.

[D.1](#). Resource Retrieval Examples

[D.1.1](#). Retrieve the Top-level API Resource

The client may start by retrieving the top-level API resource, using the entry point URI "{+restconf}".

```
GET /restconf HTTP/1.1
Host: example.com
Accept: application/yang.api+json,
       application/yang.errors+json
```

The server might respond as follows:

```
HTTP/1.1 200 OK
Date: Mon, 23 Apr 2012 17:01:00 GMT
Server: example-server
Content-Type: application/yang.api+json
```

```
{
  "ietf-restconf:restconf": {
    "data" : [ null ],
    "modules": {
      "module": [
        {
          "name" : "example-jukebox",
          "revision" : "2014-07-03",
          "namespace" : "http://example.com/ns/example-jukebox",
          "schema" : [ null ]
        }
      ]
    },
    "operations" : {
      "play" : [ null ]
    },
    "streams" : {
      "stream" : [
        {
          "name" : "NETCONF",
          "description" : "default NETCONF event stream",
          "replay-support" : true,
          "replay-log-creation-time:" : "2007-07-08T00:00:00Z",
          "events" : [ null ]
        }
      ]
    }
  }
}
```

To request that the response content to be encoded in XML, the "Accept" header can be used, as in this example request:

```
GET /restconf HTTP/1.1
Host: example.com
Accept: application/yang.api+xml,
       application/yang.errors+xml
```

The server will return the same response either way, which might be as follows :

```
HTTP/1.1 200 OK
Date: Mon, 23 Apr 2012 17:01:00 GMT
Server: example-server
Cache-Control: no-cache
Pragma: no-cache
Content-Type: application/yang.api+xml
```

```

      <events/>
    </stream>
  </streams>
</restconf>
```

[D.1.2.](#) Retrieve The Server Module Information

In this example the client is retrieving the modules resource from the server in JSON format:

```
GET /restconf/modules HTTP/1.1
Host: example.com
Accept: application/yang.api+json,
        application/yang.errors+json
```

The server might respond as follows.

```
HTTP/1.1 200 OK
Date: Mon, 23 Apr 2012 17:01:00 GMT
Server: example-server
Cache-Control: no-cache
Pragma: no-cache
Last-Modified: Sun, 22 Apr 2012 01:00:14 GMT
Content-Type: application/yang.api+json
```

```
{
  "ietf-restconf:modules": {
    "module": [
      {
        "name" : "foo",
        "revision" : "2012-01-02",
        "schema" : [null],
        "namespace" : "http://example.com/ns/foo",
        "feature" : [ "feature1", "feature2" ]
      },
      {
        "name" : "foo-types",
        "revision" : "2012-01-05",
        "schema" : [null],
        "namespace" : "http://example.com/ns/foo-types"
      },
      {
        "name" : "bar",
        "revision" : "2012-11-05",
        "schema" : [null],
        "namespace" : "http://example.com/ns/bar",
        "feature" : [ "bar-ext" ],
        "submodule" : [
          {
            "name" : "bar-submod1",
            "revision" : "2012-11-05",
            "schema" : [null]
          },
          {
            "name" : "bar-submod2",
            "revision" : "2012-11-05",
            "schema" : [null]
          }
        ]
      }
    ]
  }
}
```

D.2. Edit Resource Examples

D.2.1. Create New Data Resources

To create a new "artist" resource within the "library" resource, the client might send the following request.

```
POST /restconf/data/example-jukebox:jukebox/library HTTP/1.1
Host: example.com
Content-Type: application/yang.data+json

{ "example-jukebox:artist" : {
  "name" : "Foo Fighters"
}
}
```

If the resource is created, the server might respond as follows. Note that the "Location" header line is wrapped for display purposes only:

```
HTTP/1.1 201 Created
Date: Mon, 23 Apr 2012 17:02:00 GMT
Server: example-server
Location: http://example.com/restconf/data/
         example-jukebox:jukebox/library/artist=Foo%20Fighters
Last-Modified: Mon, 23 Apr 2012 17:02:00 GMT
ETag: b3830f23a4c
```

To create a new "album" resource for this artist within the "jukebox" resource, the client might send the following request. Note that the request URI header line is wrapped for display purposes only:

```
POST /restconf/data/example-jukebox:jukebox/
     library/artist=Foo%20Fighters HTTP/1.1
Host: example.com
Content-Type: application/yang.data+json

{
  "example-jukebox:album" : {
    "name" : "Wasting Light",
    "genre" : "example-jukebox:alternative",
    "year" : 2012    # note this is the wrong date
  }
}
```

If the resource is created, the server might respond as follows. Note that the "Location" header line is wrapped for display purposes only:

```
HTTP/1.1 201 Created
Date: Mon, 23 Apr 2012 17:03:00 GMT
Server: example-server
Location: http://example.com/restconf/data/
         example-jukebox:jukebox/library/artist=Foo%20Fighters/
         album=Wasting%20Light
Last-Modified: Mon, 23 Apr 2012 17:03:00 GMT
ETag: b8389233a4c
```

D.2.2. Detect Resource Entity Tag Change

In this example, the server just supports the mandatory datastore last-changed timestamp. The client has previously retrieved the "Last-Modified" header and has some value cached to provide in the following request to patch an "album" list entry with key value "Wasting Light". Only the "year" field is being updated.

```
PATCH /restconf/data/example-jukebox:jukebox/
      library/artist=Foo%20Fighters/album=Wasting%20Light/year
HTTP/1.1
Host: example.com
Accept: application/yang.data+json,
       application/yang.errors+json
If-Unmodified-Since: Mon, 23 Apr 2012 17:01:00 GMT
Content-Type: application/yang.data+json

{ "example-jukebox:year" : "2011" }
```

In this example the datastore resource has changed since the time specified in the "If-Unmodified-Since" header. The server might respond:

```
HTTP/1.1 412 Precondition Failed
Date: Mon, 23 Apr 2012 19:01:00 GMT
Server: example-server
Last-Modified: Mon, 23 Apr 2012 17:45:00 GMT
ETag: b34aed893a4c
```

D.3. Query String Parameter Examples

D.3.1. "content" Parameter

The "content" parameter is used to select the type of data child resources (configuration and/or not configuration) that are returned by the server for a GET method request.

In this example, a simple YANG list that has configuration and non-configuration child resources.

```
container events
  list event {
    key name;
    leaf name { type string; }
    leaf description { type string; }
    leaf event-count {
      type uint32;
      config false;
    }
  }
}
```

Example 1: content=all

To retrieve all the child resources, the "content" parameter is set to "all". The client might send:

```
GET /restconf/data/example-events:events?content=all
HTTP/1.1
Host: example.com
Accept: application/yang.data+json,
        application/yang.errors+json
```

The server might respond:

```
HTTP/1.1 200 OK
Date: Mon, 23 Apr 2012 17:11:30 GMT
Server: example-server
Cache-Control: no-cache
Pragma: no-cache
Content-Type: application/yang.data+json
```

```
{
  "example-events:events" : {
    "event" : [
      {
        "name" : "interface-up",
        "description" : "Interface up notification count",
        "event-count" : 42
      },
      {
        "name" : "interface-down",
        "description" : "Interface down notification count",
        "event-count" : 4
      }
    ]
  }
}
```

Example 2: content=config

To retrieve only the configuration child resources, the "content" parameter is set to "config" or omitted since this is the default value. Note that the "ETag" and "Last-Modified" headers are only returned if the content parameter value is "config".

```
GET /restconf/data/example-events:events?content=config
HTTP/1.1
Host: example.com
Accept: application/yang.data+json,
        application/yang.errors+json
```

The server might respond:

```
HTTP/1.1 200 OK
Date: Mon, 23 Apr 2012 17:11:30 GMT
Server: example-server
Last-Modified: Mon, 23 Apr 2012 13:01:20 GMT
ETag: eeeada438af
Cache-Control: no-cache
Pragma: no-cache
Content-Type: application/yang.data+json
```

```
{
  "example-events:events" : {
    "event" : [
      {
        "name" : "interface-up",
        "description" : "Interface up notification count"
      },
      {
        "name" : "interface-down",
        "description" : "Interface down notification count"
      }
    ]
  }
}
```

Example 3: content=nonconfig

To retrieve only the non-configuration child resources, the "content" parameter is set to "nonconfig". Note that configuration ancestors (if any) and list key leafs (if any) are also returned. The client might send:

```
GET /restconf/data/example-events:events?content=nonconfig
HTTP/1.1
Host: example.com
Accept: application/yang.data+json,
       application/yang.errors+json
```

The server might respond:

```
HTTP/1.1 200 OK
Date: Mon, 23 Apr 2012 17:11:30 GMT
Server: example-server
Cache-Control: no-cache
Pragma: no-cache
Content-Type: application/yang.data+json
```

```
{
  "example-events:events" : {
    "event" : [
      {
        "name" : "interface-up",
        "event-count" : 42
      },
      {
        "name" : "interface-down",
        "event-count" : 4
      }
    ]
  }
}
```

D.3.2. "depth" Parameter

The "depth" parameter is used to limit the number of levels of child resources that are returned by the server for a GET method request.

This example shows how different values of the "depth" parameter would affect the reply content for retrieval of the top-level "jukebox" data resource.

Example 1: depth=unbounded

To retrieve all the child resources, the "depth" parameter is not present or set to the default value "unbounded". Note that some strings are wrapped for display purposes only.

```
GET /restconf/data/example-jukebox:jukebox?depth=unbounded
HTTP/1.1
Host: example.com
Accept: application/yang.data+json,
       application/yang.errors+json
```

The server might respond:

```
HTTP/1.1 200 OK
Date: Mon, 23 Apr 2012 17:11:30 GMT
Server: example-server
Cache-Control: no-cache
Pragma: no-cache
Content-Type: application/yang.data+json
```

```
{
  "example-jukebox:jukebox" : {
    "library" : {
      "artist" : [
        {
          "name" : "Foo Fighters",
          "album" : [
            {
              "name" : "Wasting Light",
              "genre" : "example-jukebox:alternative",
              "year" : 2011,
              "song" : [
                {
                  "name" : "Wasting Light",
                  "location" :
                    "/media/foo/a7/wasting-light.mp3",
                  "format" : "MP3",
                  "length" " 286
                },
                {
                  "name" : "Rope",
                  "location" : "/media/foo/a7/rope.mp3",
                  "format" : "MP3",
                  "length" " 259
                }
              ]
            }
          ]
        }
      ]
    }
  },
  "playlist" : [
    {
```

```
    "name" : "Foo-One",
    "description" : "example playlist 1",
    "song" : [
      {
        "index" : 1,
        "id" : "http://example.com/restconf/data/
              example-jukebox:jukebox/library/artist/
              Foo%20Fighters/album/Wasting%20Light/
              song/Rope"
      },
      {
        "index" : 2,
        "id" : "http://example.com/restconf/data/
              example-jukebox:jukebox/library/artist/
              Foo%20Fighters/album/Wasting%20Light/song/
              Bridge%20Burning"
      }
    ]
  },
  "player" : {
    "gap" : 0.5
  }
}
```

Example 2: depth=1

To determine if 1 or more resource instances exist for a given target resource, the value "1" is used.

```
GET /restconf/data/example-jukebox:jukebox?depth=1 HTTP/1.1
Host: example.com
Accept: application/yang.data+json,
       application/yang.errors+json
```

The server might respond:

```
HTTP/1.1 200 OK
Date: Mon, 23 Apr 2012 17:11:30 GMT
Server: example-server
Cache-Control: no-cache
Pragma: no-cache
Content-Type: application/yang.data+json

{
  "example-jukebox:jukebox" : [null]
}
```

Example 3: depth=3

To limit the depth level to the target resource plus 2 child resource layers the value "3" is used.

```
GET /restconf/data/example-jukebox:jukebox?depth=3 HTTP/1.1
Host: example.com
Accept: application/yang.data+json,
       application/yang.errors+json
```

The server might respond:

```
HTTP/1.1 200 OK
Date: Mon, 23 Apr 2012 17:11:30 GMT
Server: example-server
Cache-Control: no-cache
Pragma: no-cache
Content-Type: application/yang.data+json
```

```
{
  "example-jukebox:jukebox" : {
    "library" : {
      "artist" : [ null ]
    },
    "playlist" : [
      {
        "name" : "Foo-One",
        "description" : "example playlist 1",
        "song" : [ null ]
      }
    ],
    "player" : {
      "gap" : 0.5
    }
  }
}
```

[D.3.3.](#) "filter" Parameter

The following URIs show some examples of notification filter specifications (lines wrapped for display purposes only):

```

// filter = /event/eventClass='fault'
GET /restconf/streams/stream=NETCONF/events?
    filter=%2Fevent%2FeventClass%3D'fault'

// filter = /event/severityCode<=4
GET /restconf/streams/stream=NETCONF/events?
    filter=%2Fevent%2FseverityCode%3C%3D4

// filter = /linkUp|/linkDown
GET /restconf/streams/stream=SNMP/events?
    filter=%2FlinkUp%7C%2FlinkDown

// filter = */reportingEntity/card!='Ethernet0'
GET /restconf/streams/stream=NETCONF/events?
    filter=%2F*%2FreportingEntity%2Fcard%21%3D'Ethernet0'

// filter = */email-addr[contains(.,'company.com')]
GET /restconf/streams/stream=critical-syslog/events?
    filter=%2F*%2Femail-addr[contains(.%2C'company.com')]

// Note: the module name is used as prefix.
// filter = (/example-mod:event1/name='joe' and
//           /example-mod:event1/status='online')
GET /restconf/streams/stream=NETCONF/events?
    filter=(%2Fexample-mod%3Aevent1%2Fname%3D'joe'%20and
            %20%2Fexample-mod%3Aevent1%2Fstatus%3D'online')

```

D.3.4. "insert" Parameter

In this example, a new first entry in the "Foo-One" playlist is being created.

Request from client:

```

POST /restconf/data/example-jukebox:jukebox/
    playlist=Foo-One?insert=first HTTP/1.1
Host: example.com
Content-Type: application/yang.data+json

{
  "example-jukebox:song" : {
    "index" : 1,
    "id" : "/example-jukebox:jukebox/library/artist/
        Foo%20Fighters/album/Wasting%20Light/song/Rope"
  }
}

```

Response from server:

```
HTTP/1.1 201 Created
Date: Mon, 23 Apr 2012 13:01:20 GMT
Server: example-server
Last-Modified: Mon, 23 Apr 2012 13:01:20 GMT
Location: http://example.com/restconf/data/
          example-jukebox:jukebox/playlist=Foo-One/song=1
ETag: eeeada438af
```

D.3.5. "point" Parameter

Example:

In this example, the client is inserting a new "song" resource within an "album" resource after another song. The request URI is split for display purposes only.

Request from client:

```
POST /restconf/data/example-jukebox:jukebox/
      library/artist/Foo%20Fighters/album/Wasting%20Light?
      insert=after&point=%2Fexample-jukebox%3Ajukebox%2F
      library%2Fartist%2FFoo%20Fighters%2Falbum%2F
      Wasting%20Light%2Fsong%2FBridge%20Burning HTTP/1.1
Host: example.com
Content-Type: application/yang.data+json
```

```
{
  "example-jukebox:song" : {
    "name" : "Rope",
    "location" : "/media/foo/a7/rope.mp3",
    "format" : "MP3",
    "length" : 259
  }
}
```

Response from server:

```
HTTP/1.1 204 No Content
Date: Mon, 23 Apr 2012 13:01:20 GMT
Server: example-server
Last-Modified: Mon, 23 Apr 2012 13:01:20 GMT
ETag: abcada438af
```

D.3.6. "select" Parameter

In this example the client is retrieving the API resource, but selecting only the "name" and "revision" nodes from each module, in JSON format:

```
GET /restconf?select=modules/module(name;revision) HTTP/1.1
Host: example.com
Accept: application/yang.api+json,
       application/yang.errors+json
```

The server might respond as follows.

```
HTTP/1.1 200 OK
Date: Mon, 23 Apr 2012 17:01:00 GMT
Server: example-server
Content-Type: application/yang.api+json
```

```
{
  "ietf-restconf:restconf": {
    "modules": {
      "module": [
        {
          "name" : "example-jukebox",
          "revision" : "2014-07-03"
        }
      ]
    }
  }
}
```

[D.3.7.](#) "start-time" Parameter

TBD

[D.3.8.](#) "stop-time" Parameter

TBD
