**YANG Library**  
**draft-ietf-netconf-rfc7895bis-01**

## Abstract

This document describes a YANG library that provides information about all the YANG modules used by a network management server (e.g., a Network Configuration Protocol (NETCONF) server). Simple caching mechanisms are provided to allow clients to minimize retrieval of this information.

## Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on March 4, 2018.

## [1. Introduction](#)

There is a need for standard mechanisms to provide the operational state of the server. This includes, for instance, identifying the YANG modules and datastores that are in use by a server and how they relate to each other.

If a large number of YANG modules are utilized by the server, then the YANG library contents needed can be relatively large. This information changes very infrequently, so it is important that clients be able to cache the YANG library contents and easily identify whether their cache is out of date.

YANG library information can be different on every server and can change at runtime or across a server reboot.

If the server implements multiple protocols to access the YANG-defined data, each such protocol has its own conceptual instantiation of the YANG library.

Bierman, et al.

Expires March 4, 2018

[Page 2]

The following information is needed by a client application (for each YANG module in the library) to fully utilize the YANG data modeling language:

- o identifier: a unique identifier for the module that includes the module's name, revision, submodules, features, and deviations.
- o name: The name of the YANG module.
- o revision: Each YANG module and submodule within the library has a revision. This is derived from the most recent revision statement within the module or submodule. If no such revision statement exists, the module's or submodule's revision is the zero-length string.
- o submodule list: The name and revision of each submodule used by the module MUST be identified.
- o feature list: The name of each YANG feature supported by the server, in a given context, MUST be identified.
- o deviation list: The name of each YANG module used for deviation statements, in a given context, MUST be identified.

The following information is needed by a client application (for each datastore supported by the server) to fully access all the YANG-modelled data available on the server:

- o identity: the YANG identity for the datastore.
- o modules: modules supported by the datastore, including any features and deviations.

### [1.1. Terminology](#)

The keywords "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [BCP 14](#), [[RFC2119](#)].

The following terms are defined in [[RFC6241](#)]:

- o client
- o server

The following terms are defined in [[RFC7950](#)]:

Bierman, et al.

Expires March 4, 2018

[Page 3]

- o module
- o submodule

The following terms are used within this document:

- o YANG library: A collection of metadata describing the server's operational state.

### **1.2. Tree Diagrams**

A simplified graphical representation of the data model is used in this document. The meaning of the symbols in these diagrams is as follows:

- o Brackets "[" and "]" enclose list keys.
- o Abbreviations before data node names: "rw" means configuration data (read-write) and "ro" state data (read-only).
- o Symbols after data node names: "?" means an optional node, "!" means a presence container, and "\*" denotes a list and leaf-list.
- o Parentheses enclose choice and case nodes, and case nodes are also marked with a colon ":".
- o Ellipsis ("...") stands for contents of subtrees that are not shown.

### **1.3. Motivation for rfc7895bis**

RFC Ed.: delete this section, including this note, at time of publication.

All NETCONF servers supporting YANG 1.1 [[RFC7950](#)] MUST support YANG Library (see [Section 5.6.4 of RFC 7950](#)). Similarly, all RESTCONF servers MUST support YANG Library (see [Section 10 of RFC 8040](#)). These requirements are independent of if the server supports NMDA or not.

[RFC 7895](#) has a mandatory to implement 'modules-state' tree that a server uses to advertise all the modules it supports. However, this module was designed assuming the all modules would be in all datastores, and with the same number of features and deviations. However, this is not the case with NMDA-compatible servers that may have some modules that only appear in <operational> (e.g., ietf-network-topo) or only also appear in a dynamic datastore (e.g., i2rs-ephemeral-rib). It is also possible that a server only implements a

Bierman, et al.

Expires March 4, 2018

[Page 4]

module in <running>, at it hasn't yet coded support for returning the module's opstate yet. Presumably, an NMDA-supporting server would return all modules implemented in every datastore, but this would be misleading to existing clients and unhelpful to NMDA-aware clients.

In the end, it appears that the 'modules-state' node should be for non-NMDA aware clients. For backwards compatibility, an NMDA-supporting server SHOULD populate 'modules-state' in a backwards-compatible manner. The new 'yang-library' node would be ignored by legacy clients, while providing all the data needed for NMDA-aware clients, which would themselves ignore the 'modules-state' tree.

In addition to resolving the 'modules-state' node NMDA-incompatibility issue described above, the solution presented in this document is further motivated by the following desires:

- o leverage [Section 5.6.4 of RFC 7950](#) and [Section 10 of RFC 8040](#).
- o indicate which modules are supported by each datastore
- o enable the features and deviations to vary by datastore
- o structure extensible to support schema-mount
- o provide a top-level container for all server metadata

#### [1.4. Summary of Changes from RFC 7895](#)

This document updates [[RFC7895](#)] in the following ways:

- o Renames document title from "YANG Module Library" to "YANG Library".
- o Adds a new top-level "yang-library" container to hold many types of server metadata: modules supported, datastores supported, relationships between datastores and modules, etc.
- o Deprecates the "modules-state" tree.
- o Deprecates the "module-list" grouping.
- o Deprecates the "yang-library-change" notification.

## [2. YANG Library](#)

The "ietf-yang-library" module provides information about the modules used by a server. This module is defined using YANG version 1, but

it supports the description of YANG modules written in any revision of YANG.

Following is the YANG Tree Diagram for the "ietf-yang-library" module, excluding the deprecated 'modules-state' tree:

```

module: ietf-yang-library
  +-+ro yang-library
    +-+ro modules
      |  +-+ro module* [id]
      |    +-+ro id          string
      |    +-+ro name         yang:yang-identifier
      |    +-+ro revision     union
      |    +-+ro schema?      inet:uri
      |    +-+ro namespace    inet:uri
      |    +-+ro feature*     yang:yang-identifier
      |    +-+ro deviation* [name revision]
      |      |  +-+ro name      yang:yang-identifier
      |      |  +-+ro revision   union
      |    +-+ro conformance-type  enumeration
      |    +-+ro submodule* [name revision]
      |      |  +-+ro name      yang:yang-identifier
      |      |  +-+ro revision   union
      |      |  +-+ro schema?    inet:uri
    +-+ro module-sets
      |  +-+ro module-set* [id]
      |    +-+ro id          string
      |    +-+ro module*     -> ../../modules/module/id
    +-+ro datastores
      |  +-+ro datastore* [name]
      |    +-+ro name        identityref
      |    +-+ro module-set?
      |      |  -> ../../module-sets/module-set/id
    +-+ro checksum      string

  notifications:
    +-+n yang-library-update

```

## [2.1. yang-library](#)

This mandatory container holds all of the server's metadata.

### [2.1.1. yang-library/modules/module](#)

This mandatory list contains one entry for each unique instance of a module in use by the server. Each entry is distinguished by the module's name, revisions, features, and deviations.

Bierman, et al.

Expires March 4, 2018

[Page 6]

### **2.1.2. yang-library/module-sets/module-set**

This mandatory list contains one entry for each module-set in use by the server (e.g., presented by a datastore).

### **2.1.3. yang-library/datastores/datastore**

This mandatory list contains one entry for each datastore supported by the server. Each datastore entry both identifies any special properties it has and any module-sets it uses.

## **2.2. YANG Library Module**

The "ietf-yang-library" module defines monitoring information for the YANG modules used by a server.

The modules "ietf-yang-types" and "ietf-inet-types" from [[RFC6991](#)] and the module "ietf-datastores" from [[I-D.ietf-netmod-revised-datastores](#)] are used by this module for some type definitions.

RFC Ed.: update the date below with the date of RFC publication and remove this note.

                "Indicates that the server implements one or more
                protocol-accessible objects defined in the YANG module
                identified in this entry. This includes deviation
                statements defined in the module.

                For YANG version 1.1 modules, there is at most one
                module entry with conformance type 'implement' for a
                particular module name, since YANG 1.1 requires that
                at most one revision of a module is implemented.

                For YANG version 1 modules, there SHOULD NOT be more
                than one module entry for a particular module name.";

### **3. IANA Considerations**

#### **3.1. YANG Module Registry**

[RFC 7895](#) previously registered one URI in the IETF XML registry [[RFC3688](#)]. Following the format in [RFC 3688](#), the following registration was made:

URI: urn:ietf:params:xml:ns:yang:ietf-yang-library  
Registrant Contact: The NETCONF WG of the IETF.  
XML: N/A, the requested URI is an XML namespace.

This document takes over this registration entry made by [RFC 7895](#).

[RFC 7895](#) previously registered one YANG module in the "YANG Module Names" registry [[RFC6020](#)] as follows:

name:	ietf-yang-library
namespace:	urn:ietf:params:xml:ns:yang:ietf-yang-library
prefix:	yanglib
reference:	<a href="#">RFC 7895</a>

This document takes over this registration entry made by [RFC 7895](#).

### **4. Security Considerations**

The YANG module defined in this memo is designed to be accessed via the NETCONF protocol [[RFC6241](#)]. The lowest NETCONF layer is the secure transport layer and the mandatory-to-implement secure transport is SSH [[RFC6242](#)]. The NETCONF access control model [[RFC6536](#)] provides the means to restrict access for particular

NETCONF users to a pre-configured subset of all available NETCONF protocol operations and content.

Some of the readable data nodes in this YANG module may be considered sensitive or vulnerable in some network environments. It is thus important to control read access (e.g., via get, get-config, or notification) to these data nodes. These are the subtrees and data nodes and their sensitivity/vulnerability:

- o /modules-state/module: The module list used in a server implementation may help an attacker identify the server capabilities and server implementations with known bugs. Although some of this information may be available to all users via the NETCONF <hello> message (or similar messages in other management protocols), this YANG module potentially exposes additional details that could be of some assistance to an attacker. Server vulnerabilities may be specific to particular modules, module revisions, module features, or even module deviations. This information is included in each module entry. For example, if a particular operation on a particular data node is known to cause a server to crash or significantly degrade device performance, then the module list information will help an attacker identify server implementations with such a defect, in order to launch a denial-of-service attack on the device.
