EAP Attributes for Wi-Fi - EPC Integration draft-ietf-netext-wifi-epc-eap-attributes-14

Abstract

With Wi-Fi emerging as a crucial access network for mobile service providers, it has become important to provide functions commonly available in 3G and 4G networks in Wi-Fi access networks as well. Such functions include Access Point Name (APN) Selection, multiple Packet Data Network (PDN) connections, and seamless mobility between Wi-Fi and 3G/4G networks.

The EAP-AKA (and EAP-AKA') protocol is required for mobile devices to access the mobile Evolved Packet Core (EPC) via Wi-Fi networks. This document defines a few new EAP attributes to enable the abovementioned functions in such networks. The attributes are exchanged between a client (such as a Mobile Node) and its network counterpart (such as a AAA server) in the service provider's infrastructure.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of \underline{BCP} 78 and \underline{BCP} 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at http://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on May 18, 2015.

1. Introduction

Wi-Fi has emerged as a "trusted" access technology for mobile service providers; see [EPC2] for reference to the 3GPP description of "trusted" access. Advances in IEEE 802.11u [IEEE802.11u] and "HotSpot 2.0" [hs20] have enabled seamless roaming, in which a Mobile Node can select and connect to a Wi-Fi access network just as it

would roam into a cellular network. It has thus become important to provide certain functions in Wi-Fi which are commonly supported in licensed-spectrum networks such as 3G and 4G networks. This draft specifies a few new EAP attributes for a Mobile Node (MN) to interact with the network to support some of these functions (see below). These new attributes serve as a trigger for Proxy Mobile IPv6 network nodes to undertake the relevant mobility operations. For instance, when the Mobile Node requests and the network agrees for a new IP session (i.e., a new Access Point Name or APN in 3GPP), the corresponding attribute (defined below) acts as a trigger for the Mobile Anchor Gateway (MAG) to initiate a new mobility session with the Local Mobility Anchor (LMA). This document refers to [RFC6459] for the basic definitions of mobile network terminology (such as APN) used here.

The 3rd Generation Partnership Project (3GPP) networks support many functions that are not commonly implemented in a Wi-Fi network. This document defines EAP attributes that enable the following functions in Wi-Fi access networks using EAP-AKA' [RFC5448] and EAP-AKA [RFC4187]:

- o APN Selection
- o Multiple APN Connectivity
- o Wi-Fi to 3G/4G (UTRAN/EUTRAN) mobility

The attributes defined here are exchanged between the Mobile Node and the EAP server, typically realized as part of the AAA server infrastructure in a service provider's infrastructure. In particular, the Wi-Fi access network simply conveys the attributes to the service provider's core network where the EAP processing takes place [EPC]. Since these attributes share the same IANA registry, the methods are applicable to EAP-AKA', EAP-AKA, EAP-SIM [RFC4186] and, with appropriate extensions, are possibly applicable for other EAP methods as well. In addition to the trusted Wi-Fi access networks, the attributes are applicable to any trusted "non-3GPP" access network that uses the EAP methods and provides connectivity to the mobile EPC, which provides connectivity for 3G, 4G, and other non-3GPP access networks [EPC2].

1.1. APN Selection

The 3GPP networks support the concept of an APN (Access Point Name). This is defined in [GPRS]. Each APN is an independent IP network with its own set of IP services. When the MN attaches to the network, it may select a specific APN to receive desired services. For example, to receive generic Internet services, a user device may

select APN "Internet" and to receive IMS voice services, it may select APN "IMSvoice".

In a Wi-Fi access scenario, an MN needs a way of sending the desired APN name to the network. This draft specifies a new attribute to propagate the APN information via EAP. The agreed APN is necessary for the Proxy Mobile IPv6 MAG to initiate a new session with the LMA.

1.2. Multiple APN Connectivity

As an extension of APN Selection, an MN may choose to connect to multiple IP networks simultaneously. 3GPP provides this feature via additional Packet Data Protocol (PDP) contexts or additional Packet Data Network (PDN) connections, and defines the corresponding set of signaling procedures. In a trusted Wi-Fi network, an MN connects to the first APN via DHCPv4 or IPv6 Router Solicitation. This document specifies an attribute that indicates the MN's capability to support multiple APN connectivity. The specific connectivity types are also necessary for the Proxy Mobile IPv6 signaling.

1.3. Wi-Fi to E-UTRAN mobility

When operating in a multi-access network, an MN may want to gracefully handover its IP attachment from one access network to another. For instance, an MN connected to a 3GPP E-UTRAN network may choose to move its connectivity to a trusted Wi-Fi network. Alternatively, the MN may choose to connect using both access technologies simultaneously, and maintain two independent IP attachments. To implement these scenarios, the MN needs a way to correlate the UTRAN/E-UTRAN session with the new Wi-Fi session. This draft specifies an attribute to propagate E-UTRAN session identification to the network via EAP. This helps the network to correlate the sessions between the two Radio Access Network technologies and thus helps the overall handover process.

2. Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

3. Protocol Overview

3.1. Brief Introduction to EAP

EAP is defined as a generic protocol in [RFC3748]. EAP, combined with one of the payload protocols such as EAP-AKA' [RFC5448] can accomplish several things in a network:

- o Establish identity of the user (MN) to the network.
- o Authenticate the user during the first attach with the help of an authentication center that securely maintains the user credentials. This process is called EAP Authentication.
- o Re-authenticate the user periodically, but without the overhead of a round-trip to the authentication center. This process is called EAP Fast Re-Authentication.

This draft makes use of the EAP Authentication procedure. The use of EAP Fast Re-Authentication procedure is for further study. Both the EAP Authentication and EAP Fast Re-Authentication procedures are specified for trusted access network use in 3GPP. [TS-33.402]

3.2. IEEE 802.11 Authentication using EAP over 802.1X

In a Wi-Fi network, EAP is carried over the IEEE 802.1X Authentication protocol. The IEEE 802.1X Authentication is a transparent, payload-unaware mechanism to carry the authentication messages between the MN and the Wi-Fi network elements.

EAP, on the other hand, has multiple purposes. Apart from its core functions of communicating an MN's credentials to the network and proving the MN's identity, it also allows the MN to send arbitrary information elements to help establish the MN's IP session in the network. The following figure shows an example end-to-end EAP flow in the context of an IEEE 802.11 Wi-Fi network. We first define the terminology:

o MN: Mobile Node

o WAP: Wi-Fi Access Point

- o WAC: Wi-Fi Access Controller. In a PMIPv6 [RFC5213] network, hosts the MAG functionality or is assumed to have a suitable interface to the MAG. In the following, we simply use "WAC" notation. The MAG functionality within the WAC (or within the Wi-Fi access network), or a suitable interface to the MAG is assumed for PMIPv6 deployments.
- o IPCN: IP Core Network. This includes the LMA function. It generically also includes the AAA server function.

Figure 1: Example EAP Deployment

The figure shows separate Wi-Fi Access Point and Wi-Fi Access Controller, following the split-MAC model of CAPWAP [RFC5415]. A particular deployment may have the two functions within a single node.

- 1. An MN detects a beacon from a WAP in the vicinity.
- 2. The MN probes the WAP to determine suitability to attach (Verify SSID list, authentication type and so on).
- 3. The MN initiates the IEEE 802.11 Authentication with the Wi-Fi network. In WPA/WPA2 mode, this is an open authentication without any security credential verification.
- 4. The MN initiates 802.11 Association with the Wi-Fi network.
- 5. The Wi-Fi network initiates 802.1X/EAP Authentication procedures by sending EAP Request/Identity.
- 6. The MN responds with its permanent or temporary identity.

- 7. The Wi-Fi network challenges the MN to prove its identity by sending EAP Request/AKA-Challenge.
- 8. The MN calculates the security digest and responds with EAP Response/AKA-Challenge.
- 9. If the authentication is successful, the Wi-Fi network responds to the MN with EAP Success.
- 10. An end-to-End data path is available for the MN to start IP layer communication (DHCPv4, IPv6 Router Solicitation and so on).

4. New EAP Attributes

The following sections define the new EAP attributes and their usage.

4.1. APN Selection

In a Wi-Fi network, an MN includes the AT_VIRTUAL_NETWORK_ID attribute in the EAP-Response/AKA-Challenge to indicate the desired APN identity for the first PDN connection.

If the MN does not include the AT_VIRTUAL_NETWORK_ID attribute in the EAP-Response/AKA-Challenge, the network may select an APN by other means. This selection mechanism is outside the scope of this document.

An MN includes the AT_VIRTUAL_NETWORK_REQ attribute to indicate single or multiple PDN capability. In addition, a sub-type in the attribute indicates IPv4, IPv6, or dual IPv4v6 PDN connectivity.

4.2. Connectivity Type

An MN indicates its preference for connectivity using the AT_CONNECTIVITY_TYPE attribute in the EAP-Response/AKA-Challenge message. The preference indicates whether the MN wishes connectivity to the Evolved Packet Core (the so-called "EPC PDN connectivity") or Internet Offload (termed as "Non-Seamless Wireless Offload").

The network makes its decision and replies with the same attribute in the EAP Success message.

4.3. Wi-Fi to UTRAN/E-UTRAN Mobility

When a multi-access MN enters a Wi-Fi network, the following parameters are applicable in the EAP-Response/AKA-Challenge for IP session continuity from UTRAN/E-UTRAN.

- o AT_HANDOVER_INDICATION: This attribute indicates to the network that the MN intends to continue the IP session from UTRAN/E-UTRAN. If a previous session can be located, network will honor this request by connecting the Wi-Fi access to the existing IP session.
- o AT_HANDOVER_SESSION_ID: An MN MAY use this attribute to identify the session on UTRAN/E-UTRAN. If used, this attribute contains P-TMSI (Packet Temporary Mobile Subscriber Identity) if the previous session was on UTRAN or M-TMSI (Mobile Temporary Mobile Subscriber Identity) if the previous session was on E-UTRAN. This attribute helps the network correlate the Wi-Fi session to an existing UTRAN/E-UTRAN session.

4.4. MN Serial ID

The MN_SERIAL_ID attribute defines an MN's serial number, including International Mobile Equipment Identity (IMEI) and International Mobile Equipment Identity Software Version (IMEISV). The IMEI (or IMEISV) is used for ensuring a legitimate (and not a stolen) device is in use. As with the others, this attribute is exchanged with the service provider's AAA server. The MN_SERIAL_ID MUST NOT be propagated further by the AAA server to any other node.

5. Attribute Extensions

The format for the new attributes follows that in [RFC4187]. Note that the Length field value is inclusive of the first two bytes.

5.1. AT_VIRTUAL_NETWORK_ID

The AT_VIRTUAL_NETWORK_ID attribute identifies the virtual IP network that the MN intends to attach to. The implementation of the virtual network on the core network side is technology specific. For instance, in a 3GPP network, the virtual network is implemented based on the 3GPP APN primitive.

This attribute SHOULD be included in the EAP-Response/AKA-Challenge message.

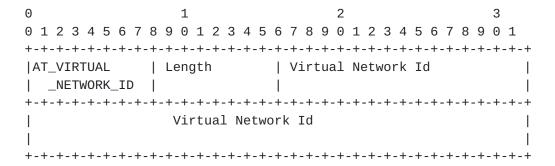

Figure 2: AT_VIRTUAL_NETWORK_ID EAP Attribute

Virtual Network Id:

An arbitrary octet string that identifies a virtual network in the access technology the MN is attaching to. For instance, in 3GPP E-UTRAN, this could be an APN. See [TS-23.003] for encoding of the field.

5.2. AT_VIRTUAL_NETWORK_REQ

When an MN intends to connect an APN, it SHOULD use this attribute to indicate different capabilities to the network. In turn, the network provides what is supported.

From the MN, this attribute can be included only in EAP-Response/ Identity. From the network, it SHOULD be included in the EAP Request/AKA-Challenge message. In the MN-to-network direction, the Type field (below) indicates the MN's request. In the network-to-MN direction, the Type field indicates network's willingness to support the request; a present Type field value indicates the network support for that Type.

Figure 3: AT_VIRTUAL_NETWORK_REQ EAP Attribute

Virt-Net-Req Type:

Type can have one of the following values:

o TBA IANA: Reserved

- o TBA IANA: Single PDN connection
- o TBA IANA: Multiple PDN connection. Can request Non-Seamless Wi-Fi Offload or EPC connectivity (see the Connectivity Type attribute below)

Virt-Net-Req Sub-type:

Sub-type can have one of the following values:

o TBA IANA: Reserved

o TBA IANA: PDN Type: IPv4

o TBA IANA: PDN Type: IPv6

o TBA IANA : PDN Type: IPv4v6

5.3. AT_CONNECTIVITY_TYPE

An MN uses this attribute to indicate whether it wishes the connectivity type to be Non-Seamless WLAN Offload or EPC. This attribute is applicable for multiple PDN connections only.

From the MN, this attribute can be included only in EAP-Response/ Identity. From the network, it SHOULD be included in the EAP Request/AKA-Challenge message.

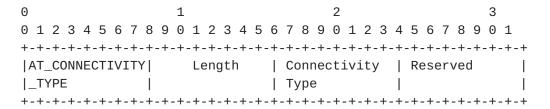

Figure 4: AT_CONNECTIVITY_TYPE EAP Attribute

Connectivity Type:

Connectivity Type can have one of the following values:

o TBA IANA: Reserved

o TBA IANA: Non-Seamless WLAN Offload (NSWO)

o TBA IANA: EPC PDN connectivity

5.4. AT_HANDOVER_INDICATION

This attribute indicates an MN's handover intention of an existing IP attachment.

This attribute SHOULD be included in the EAP-Response/AKA-Challenge message.

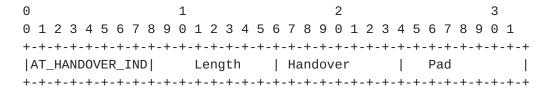

Figure 5: AT_HANDOVER_INDICATION EAP Attribute

Handover Type:

- o 0 the MN has no intention of handing over an existing IP session, i.e., the MN is requesting an independent IP session with the Wi-Fi network without disrupting the IP session with the UTRAN/E-UTRAN. In this case, no Session Id (Section 5.5) is included.
- o 1 the MN intends to handover an existing IP session. In this case, MN MAY include a Session Id (<u>Section 5.5</u>) to correlate this Wi-Fi session with a UTRAN/E-UTRAN session.

5.5. AT_HANDOVER_SESSION_ID

When an MN intends to handover an earlier IP session to the current access network, it may propagate a session identity that can help identify the previous session from UTRAN/E-UTRAN that the MN intends to handover. This attribute is defined as a generic octet string. The MN MAY include an E-UTRAN GUTI if the previous session was an E-UTRAN session. If the previous session was a UTRAN session, the MN MAY include UTRAN Global RNC ID (MCC, MNC, RNC Id) and P-TMSI concatenated as an octet string.

This attribute SHOULD be included in the EAP-Response/AKA-Challenge message.

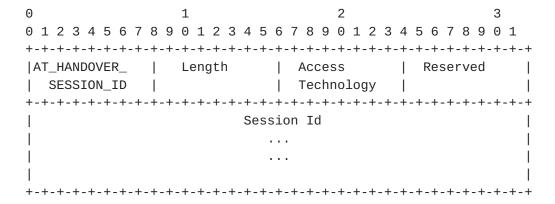

Figure 6: AT_HANDOVER_SESSION_ID EAP Attribute

Access Technology:

This field represents the RAN technology from which the MN is undergoing a handover.

o TBA IANA: Reserved

o TBA IANA: UTRAN

o TBA IANA: E-UTRAN

Session Id:

An octet string of variable length that identifies the session in the source access technology. As defined at the beginning of this section, the actual value is RAN technology dependent. For E-UTRAN, the value is GUTI. For UTRAN, the value is Global RNC Id (6 bytes) followed by P-TMSI (4 bytes). See [TS-23.003] for encoding of the field.

5.6. AT_MN_SERIAL_ID

This attribute defines the MN's machine serial number. Examples are International Mobile Equipment Identity (IMEI) and International Mobile Equipment Identity Software Version (IMEISV).

A network that requires the machine serial number for authorization purposes can send a request for the attribute in an EAP-Request/AKA-Challenge message. If the request is present, the MN SHOULD include the attribute in the EAP-Response/AKA-Challenge message. An MN MUST NOT provide the attribute unless it receives a request for it from an authenticated network.

0	1	2	3
0 1 2 3 4 5 6 7 8 9	0 1 2 3 4 5 6 7	7 8 9 0 1 2 3	4 5 6 7 8 9 0 1
+-+-+-+-+-+-+-+-+	-+-+-+-+-+-	+-+-+-+-+-	+-+-+-+-+-+-+
AT_MN_	Length	Serial ID	Reserved
SERIAL_ID		Type	
+-+-+-+-+-+-+-+-+	-+-+-+-+-+-	+-+-+-+-+-	+-+-+-+-+-+-+
	MN Seri	ial Id	
+-+-+-+-+-+-+-+-+	-+-+-+-+-+-+-+	+-+-+-+-+-	+-+-+-+-+-+-+

Figure 7: AT_MN_SERIAL_ID EAP Attribute

Serial ID Type:

This field identifies the type of the MN Identifier.

o TBA IANA: Reserved

o TBA IANA: IMEI

o TBA IANA: IMEISV

MN Serial Id:

An arbitrary octet string that identifies the MN's machine serial number. The actual value is device-specific. See [TS-23.003] for encoding of the field. When sent by the network in the EAP-Request/ AKA-Challenge message, this field is not present, which serves as an indication for the MN to provide the attribute in the EAP-Response/ AKA-Challenge message.

AT_MN_SERIAL_ID attribute MUST only be used with methods which can provide mutual (network and device) authentication, such as AKA, AKA' and EAP-SIM.

6. Security Considerations

This document defines new EAP attributes to extend the capability of the EAP-AKA protocol as specified in <u>Section 8.2 of [RFC4187]</u>. The attributes are passed between an MN and a AAA server in provider-controlled trusted Wi-Fi networks. The document does not specify any new messages or options to the EAP-AKA protocol.

The attributes defined here are fields which are used in existing 3G and 4G networks, where they are exchanged (in protocols specific to 3G and 4G networks) subsequent to the mobile network authentication (e.g., using the UMTS-AKA mechanism). For the operator-controlled Wi-Fi access which is connected to the same core infrastructure as the

3G and 4G access, similar model is followed here with the EAP-AKA (or EAP-AKA', EAP-SIM) authentication. In doing so, these attribute processing, security-wise, is no worse than that in existing 3G and 4G mobile networks.

The attributes inherit the security protection (integrity, replay, and confidentiality) provided by the paratmeters in the AKA(') or SIM methods; see Section 12.6 in [RFC4187]. Furthermore, RFC 4187 requires attributes exchanged in EAP-Request/AKA-Identity or EAP-Response/AKA-Identity to be integrity-protected with AT_CHECKCODE; see Section 8.2 in [RFC4187]. This requirement applies to the AT_CONNECTIVITY_TYPE and AT_VIRTUAL_NETWORK_REQ attributes defined in this document.

The AT_MN_SERIAL_ID attribute MUST have confidentiality protection provided by the AKA(') or EAP-SIM methods beyond the secure transport (such as private leased lines, VPN etc.) deployed by the provider of the trusted Wi-Fi service.

7. IANA Considerations

This document defines the following new skippable EAP-AKA attributes. These attributes need assignments from the "EAP-AKA and EAP-SIM Parameters" registry at https://www.iana.org/assignments/eapsimaka-numbers

- o AT_VIRTUAL_NETWORK_ID (Section 5.1) TBA by IANA
- o AT_VIRTUAL_NETWORK_REQ (Section 5.2) TBA by IANA
- o AT_CONNECTIVITY_TYPE (Section 5.3) TBA IANA
- o AT_HANDOVER_INDICATION (Section 5.4) TBA by IANA
- o AT_HANDOVER_SESSION_ID (Section 5.5) TBA by IANA
- o AT_MN_SERIAL_ID (<u>Section 5.6</u>) TBA by IANA

This document requests a new IANA registry "Trusted non-3GPP Access EAP Parameters". The range for both Types and Sub types in the registry is 0 - 127, with 0 (zero) being a reserved value. The document requests IANA to make assignments in a monotonically increasing order in increments of 1, starting from 1. New assignments in this registry are made with the Specification Required policy [RFC5226].

The IANA Designated Expert should review the requirements for new assignments based on factors including, but not limited to, the

source of request (e.g., standards bodies), deployment needs (e.g., industry consortium, operator community) and experimental needs (e.g., academia, industrial labs). A document outlining the purpose of new assignments should accompany the request. Such a document could be a standards document, or a research project description. The Designated Expert should consider that there is sufficient evidence of potential usage both on the end-points (e.g., Mobile Devices etc.) and the infrastructure (e.g., AAA servers, gateways etc.)

The document requests assignments from the new registry for the following fields defined in this document:

- o Virt-Net-Req Type (Section 5.2) TBA by IANA
- o Virt-Net-Req Sub type (Section 5.2) TBA by IANA
- o Connectivity Type (<u>Section 5.3</u>) TBA IANA
- o Access Technology (Section 5.5) TBA by IANA
- o Serial ID Type (Section 5.6) TBA by IANA

8. Acknowledgment

Thanks to Sebastian Speicher for the review and suggesting improvements. Thanks to Mark Grayson for proposing the MN Serial ID attribute. And, thanks to Brian Haberman for suggesting a new registry.

Appendix A. Change Log

- o: Initial Draft
- o: v01: status to Informational, Updated References, Revised the Figure
- o: No changes from 01 to 02
- o: Per recent 3GPP updates, added the Connectivity Type attribute to allow indicating Non-Seamless WLAN Offload or EPC connectivity
- o: version-04: Revised AT_VIRTUAL_NETWORK_REQ to include 1) single PDN vs Multiple PDN connections, 2) PDN Types, and referred to NSWO Connectivity Type attribute
- o: version 05: Added AT_MN_SERIAL_ID. Revised the IANA Considerations section
- o: version 06, 07: various edits
- o: AD review revs
- o: version 09: IETF LC, Directorate review revs
- o: IANA Section revision, based on IANA interaction
- o: version 12 clarified/revised: 1) IMEI purpose, 2) attributes requirement in PMIP6 signaling, 3) references to 802.11u, HotSpot 2.0 (seamless roaming) 4) References (normative/informative), 5) editorial corrections

- o: version 13 revised AT_MN_SERIAL_ID processing per IESG DISCUSS
- o: version 14 -clarified usage of AT_MN_SERIAL_ID. Provided additional reference to "trusted" Wi-Fi access.
