A YANG Data Model for Interface Management  
draft-ietf-netmod-interfaces-cfg-16

## Abstract

This document defines a YANG data model for the management of network interfaces. It is expected that interface type specific data models augment the generic interfaces data model defined in this document. The data model includes configuration data and state data (status information and counters for the collection of statistics).

## Status of this Memo

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on July 27, 2014.

## 1. Introduction

This document defines a YANG [[RFC6020](#)] data model for the management of network interfaces. It is expected that interface type specific data models augment the generic interfaces data model defined in this document.

Network interfaces are central to the management of many Internet protocols. Thus, it is important to establish a common data model for how interfaces are identified, configured, and monitored.

The data model includes configuration data and state data (status information and counters for the collection of statistics).

### 1.1. Terminology

The keywords "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [BCP 14](#), [[RFC2119](#)].

The following terms are used within this document:

- o system-controlled interface: An interface is said to be system-controlled if the system creates and deletes the interface independently of what has been explicitly configured. Examples are interfaces representing physical hardware that appear and disappear when hardware (e.g., a line card or hot pluggable wireless interface) is added or removed. System-controlled interfaces may also appear if a certain functionality is enabled (e.g., a loopback interface might appear if the IP protocol stack is enabled).
- o user-controlled interface: An interface is said to be user-controlled if the creation of the interface is controlled by adding explicit interface configuration to the running

configuration datastore and the removal of the interface is controlled by removing explicit interface configuration from the running configuration datastore. Examples are VLAN interfaces configured on a system-controlled Ethernet interface.

The following terms are defined in [[RFC6241](#)] and are not redefined here:

- o client
- o configuration data

- o server
- o state data

The following terms are defined in [[RFC6020](#)] and are not redefined here:

- o augment
- o data model
- o data node
- o presence container

## [1.2.](#) Tree Diagrams

A simplified graphical representation of the data model is used in this document. The meaning of the symbols in these diagrams is as follows:

- o Brackets "[" and "]" enclose list keys.
- o Abbreviations before data node names: "rw" means configuration (read-write) and "ro" state data (read-only).
- o Symbols after data node names: "?" means an optional node, "!" means a presence container, and "\*" denotes a list and leaf-list.

- o Parentheses enclose choice and case nodes, and case nodes are also marked with a colon (":").
- o Ellipsis ("...") stands for contents of subtrees that are not shown.

## [2.](#) Objectives

This section describes some of the design objectives for the model presented in [Section 5](#).

- o It is recognized that existing implementations will have to map the interface data model defined in this memo to their proprietary native data model. The data model should be simple to facilitate such mappings.
- o The data model should be suitable for new implementations to use as-is, without requiring a mapping to a different native model.
- o References to interfaces should be as simple as possible, preferably by using a single leafref.
- o The mapping to ifIndex [[RFC2863](#)] used by SNMP to identify interfaces must be clear.
- o The model must support interface layering, both simple layering where one interface is layered on top of exactly one other interface, and more complex scenarios where one interface results

from the aggregation of N other interfaces, or when N interfaces are multiplexed over one other interface.

- o The data model should support the pre-provisioning of interface configuration, i.e., it should be possible to configure an interface whose physical interface hardware is not present on the device. It is recommended that devices that support dynamic addition and removal of physical interfaces also support pre-provisioning.
- o The data model should support both physical interfaces as well as logical interfaces.
- o The data model should include read-only counters in order to gather statistics for sent and received octets and packets, received packets with errors, and packets that could not be sent due to errors.

### [3.](#) Interfaces Data Model

This document defines the YANG module "ietf-interfaces", which has the following structure:

```
+--rw interfaces
|  +--rw interface* [name]
|    +--rw name                string
|    +--rw description?        string
|    +--rw type                 identityref
|    +--rw enabled?            boolean
|    +--rw link-up-down-trap-enable? enumeration
+--ro interfaces-state
  +--ro interface* [name]
    +--ro name                  string
```

+--ro type	identityref
+--ro admin-status	enumeration
+--ro oper-status	enumeration
+--ro last-change?	yang:date-and-time
+--ro if-index	int32
+--ro phys-address?	yang:phys-address
+--ro higher-layer-if*	interface-state-ref
+--ro lower-layer-if*	interface-state-ref
+--ro speed?	yang:gauge64
+--ro statistics	
+--ro discontinuity-time	yang:date-and-time
+--ro in-octets?	yang:counter64
+--ro in-unicast-pkts?	yang:counter64
+--ro in-broadcast-pkts?	yang:counter64
+--ro in-multicast-pkts?	yang:counter64
+--ro in-discards?	yang:counter32
+--ro in-errors?	yang:counter32
+--ro in-unknown-protos?	yang:counter32
+--ro out-octets?	yang:counter64
+--ro out-unicast-pkts?	yang:counter64
+--ro out-broadcast-pkts?	yang:counter64
+--ro out-multicast-pkts?	yang:counter64
+--ro out-discards?	yang:counter32
+--ro out-errors?	yang:counter32

### [3.1.](#) The interface Lists

The data model for interfaces presented in this document uses a flat list of interfaces. Each interface in the list is identified by its name. Furthermore, each interface has a mandatory "type" leaf.

The "iana-if-type" module [[I-D.ietf-netmod-iana-if-type](#)] defines YANG identities for the interface types in the IANA-maintained "ifType

registry".

There is one list of configured interfaces ("/interfaces/interface"), and a separate list for the operational state of all interfaces ("/interfaces-state/interface").

It is expected that interface type specific data models augment the interface lists, and possibly use the "type" leaf to make the

augmentation conditional.

As an example of such an interface type specific augmentation, consider this YANG snippet. For a more complete example, see [Appendix A](#).

```
import interfaces {
  prefix "if";
}
import iana-if-type {
  prefix ianaift;
}

augment "/if:interfaces/if:interface" {
  when "if:type = 'ianaift:ethernetCsmacd'";

  container ethernet {
    leaf duplex {
      ...
    }
  }
}
```

For system-controlled interfaces, the "name" is the device-specific name of the interface. The 'config false' list "/interfaces-state/interface" contains all existing interfaces on the device.

If the device supports arbitrarily named user-controlled interfaces, the NETCONF server advertises the feature "arbitrary-names". If the device does not advertise this feature, the names of user-controlled interfaces MUST match the device's naming scheme. How a client can learn the naming scheme of such devices is outside the scope of this document. See [Appendix E.1](#) and [Appendix E.2](#) for examples.

When a system-controlled interface is created by the system, the system tries to apply the interface configuration in "/interfaces/interface" with the same name as the new interface. If no such interface configuration is found, or if the configured type does not match the real interface type, the system creates the interface without applying explicit configuration.

When a user-controlled interface is created, the configuration

determines the name of the interface.

Depending on the operating system and the physical attachment point to which a network interface may be attached or removed, it may be impossible for an implementation to provide predictable and consistent names for system-controlled interfaces across insertion/removal cycles as well as in anticipation of initial insertion. The ability to provide configurations for such interfaces is therefore dependent on the implementation, and cannot be assumed in all cases.

### [3.2.](#) Interface References

An interface is identified by its name, which is unique within the server. This property is captured in the "interface-ref" and "interface-state-ref" typedefs, which other YANG modules SHOULD use when they need to reference a configured interface or operationally used interface, respectively.

### [3.3.](#) Interface Layering

There is no generic mechanism for how an interface is configured to be layered on top of some other interface. It is expected that interface type specific models define their own data nodes for interface layering, by using "interface-ref" types to reference lower layers.

Below is an example of a model with such nodes. For a more complete example, see [Appendix B](#).

---

```
import interfaces {
    prefix "if";
}
import iana-if-type {
    prefix ianaift;
}

augment "/if:interfaces/if:interface" {
    when "if:type = 'ianaift:ieee8023adLag'";

    leaf-list slave-if {
        type if:interface-ref;
        must "/if:interfaces/if:interface[if:name = current()]"
            + "/if:type = 'ianaift:ethernetCsmacd'" {
            description
                "The type of a slave interface must be ethernet";
        }
    }
    // other bonding config params, failover times etc.
}
```

While the interface layering is configured in type specific models, two generic state data leaf-lists, "higher-layer-if" and "lower-layer-if", represent a read-only view of the interface layering hierarchy.

#### [4.](#) Relationship to the IF-MIB

If the device implements IF-MIB [[RFC2863](#)], each entry in the `"/interfaces-state/interface"` list is typically mapped to one `ifEntry`. The `"if-index"` leaf MUST contain the value of the corresponding `ifEntry`'s `ifIndex`.

In most cases, the `"name"` of an `"/interfaces-state/interface"` entry is mapped to `ifName`. The IF-MIB allows two different `ifEntries` to have the same `ifName`. Devices that support this feature, and also support the data model defined in this document, cannot have a 1-1 mapping between the `"name"` leaf and `ifName`.

The configured `"description"` of an `"interface"` has traditionally been mapped to `ifAlias` in some implementations. This document allows this mapping, but implementers should be aware of the differences in the value space and persistence for these objects. See the YANG module definition of the leaf `"description"` in [Section 5](#) for details.

The IF-MIB also defines the writable object `ifPromiscuousMode`. Since this object typically is not implemented as a configuration object by SNMP agents, it is not mapped to the `"ietf-interfaces"` module.

The `ifMtu` object from IF-MIB is not mapped to the `"ietf-interfaces"` module. It is expected that interface type specific YANG modules provide interface type specific MTU leaves by augmenting the `"ietf-interfaces"` model.

There are a number of counters in the IF-MIB that exist in two versions; one with 32 bits and one with 64 bits. The 64-bit versions were added to support high-speed interfaces with a data rate greater than 20,000,000 bits/second. Today's implementations generally support such high-speed interfaces and hence only 64-bit counters are provided in this data model. Note that NETCONF and SNMP may differ in the time granularity in which they provide access to the counters. For example, it is common that SNMP implementations cache counter values for some time.

The objects `ifDescr` and `ifConnectorPresent` from IF-MIB are not mapped

to the "ietf-interfaces" module.

The following tables list the YANG data nodes with corresponding objects in the IF-MIB.

YANG data node in /interfaces-state/interface	IF-MIB object
name	ifName
type	ifType
admin-status	ifAdminStatus
oper-status	ifOperStatus
last-change	ifLastChange
if-index	ifIndex
link-up-down-trap-enable	ifLinkUpDownTrapEnable
phys-address	ifPhysAddress
higher-layer-if and lower-layer-if	ifStackTable
speed	ifSpeed and ifHSpeed
discontinuity-time	ifCounterDiscontinuityTime
in-octets	ifHCInOctets
in-unicast-pkts	ifHCInUcastPkts
in-broadcast-pkts	ifHCInBroadcastPkts
in-multicast-pkts	ifHCInMulticastPkts
in-discards	ifInDiscards
in-errors	ifInErrors
in-unknown-protos	ifInUnknownProtos
out-octets	ifHCOutOctets
out-unicast-pkts	ifHCOutUcastPkts
out-broadcast-pkts	ifHCOutBroadcastPkts
out-multicast-pkts	ifHCOutMulticastPkts
out-discards	ifOutDiscards
out-errors	ifOutErrors

    }
}

```

```

leaf name {
    type string;
    description
        "The name of the interface."
}

```

A device MAY restrict the allowed values for this leaf, possibly depending on the type of the interface.

For system-controlled interfaces, this leaf is the device-specific name of the interface. The 'config false' list `/interfaces-state/interface` contains the currently existing interfaces on the device.

If a client tries to create configuration for a system-controlled interface that is not present in the `/interfaces-state/interface` list, the server MAY reject the request, if the implementation does not support pre-provisioning of interfaces, or if the name refers to an interface that can never exist in the system. A NETCONF server MUST reply with an `rpc-error` with the error-tag 'invalid-value' in this case.

If the device supports pre-provisioning of interface configuration, the feature 'pre-provisioning' is advertised.

If the device allows arbitrarily named user-controlled interfaces, the feature 'arbitrary-names' is advertised.

When a configured user-controlled interface is created by the system, it is instantiated with the same name in the `/interface-state/interface` list.";

}

leaf description {

  type string;

  description

    "A textual description of the interface.

A server implementation MAY map this leaf to the `ifAlias` MIB object. Such an implementation needs to use some mechanism to handle the differences in size and characters allowed between this leaf and `ifAlias`. The definition of such a mechanism is outside the scope of this document.

Since `ifAlias` is defined to be stored in non-volatile storage, the MIB implementation MUST map `ifAlias` to the value of 'description' in the persistently stored

datastore.

Specifically, if the device supports ':startup', when ifAlias is read the device MUST return the value of 'description' in the 'startup' datastore, and when it is written, it MUST be written to the 'running' and 'startup' datastores. Note that it is up to the implementation if it modifies this single leaf in 'startup', or if it performs an implicit copy-config from 'running' to 'startup'.

If the device does not support ':startup', ifAlias MUST be mapped to the 'description' leaf in the 'running' datastore.";

## 6. IANA Considerations

This document registers a URI in the IETF XML registry [[RFC3688](#)]. Following the format in [RFC 3688](#), the following registration is requested to be made.

URI: urn:ietf:params:xml:ns:yang:ietf-interfaces

Registrant Contact: The IESG.

XML: N/A, the requested URI is an XML namespace.

This document registers a YANG module in the YANG Module Names registry [[RFC6020](#)].

name:	ietf-interfaces
namespace:	urn:ietf:params:xml:ns:yang:ietf-interfaces
prefix:	if
reference:	RFC XXXX

## 7. Security Considerations

The YANG module defined in this memo is designed to be accessed via the NETCONF protocol [[RFC6241](#)]. The lowest NETCONF layer is the secure transport layer and the mandatory-to-implement secure transport is SSH [[RFC6242](#)]. The NETCONF access control model [[RFC6536](#)] provides the means to restrict access for particular NETCONF users to a pre-configured subset of all available NETCONF protocol operations and content.

There are a number of data nodes defined in the YANG module which are writable/creatable/deletable (i.e., config true, which is the default). These data nodes may be considered sensitive or vulnerable in some network environments. Write operations (e.g., <edit-config>)

to these data nodes without proper protection can have a negative effect on network operations. These are the subtrees and data nodes and their sensitivity/vulnerability:

/interfaces/interface: This list specifies the configured interfaces on a device. Unauthorized access to this list could cause the device to ignore packets it should receive and process.

/interfaces/interface/enabled: This leaf controls if an interface is enabled or not. Unauthorized access to this leaf could cause the device to ignore packets it should receive and process.

## [8.](#) Acknowledgments

The author wishes to thank Alexander Clemm, Per Hedeland, Ladislav Lhotka, and Juergen Schoenwaelder for their helpful comments.

[Appendix A](#). Example: Ethernet Interface Module

This section gives a simple example of how an Ethernet interface module could be defined. It demonstrates how media-specific configuration parameters can be conditionally augmented to the generic interface list. It also shows how operational state parameters can be conditionally augmented to the operational interface list. The example is not intended as a complete module for ethernet configuration.

```
module ex-ethernet {
  namespace "http://example.com/ethernet";
  prefix "eth";

  import ietf-interfaces {
    prefix if;
  }
  import iana-if-type {
    prefix ianaift;
  }

  // configuration parameters for ethernet interfaces
  augment "/if:interfaces/if:interface" {
    when "if:type = 'ianaift:ethernetCsmacd'";

    container ethernet {
      choice transmission-params {
        case auto {
          leaf auto-negotiate {
            type empty;
          }
        }
        case manual {
          leaf duplex {
            type enumeration {
              enum "half";
              enum "full";
            }
          }
        }
        leaf speed {
          type enumeration {
            enum "10Mb";
            enum "100Mb";
          }
        }
      }
    }
  }
}
```

```
        enum "1Gb";
        enum "10Gb";
    }
}
```

```
    }
    // other ethernet specific params...
}

// operational state parameters for ethernet interfaces
augment "/if:interfaces-state/if:interface" {
    when "if:type = 'ianaift:ethernetCsmacd'";

    container ethernet {
        leaf duplex {
            type enumeration {
                enum "half";
                enum "full";
            }
        }
        // other ethernet specific params...
    }
}
```

### [Appendix B](#). Example: Ethernet Bonding Interface Module

This section gives an example of how interface layering can be defined. An ethernet bonding interface is defined, which bonds several ethernet interfaces into one logical interface.

```
module ex-ethernet-bonding {
  namespace "http://example.com/ethernet-bonding";
  prefix "bond";

  import ietf-interfaces {
    prefix if;
  }
  import iana-if-type {
    prefix ianaift;
  }

  augment "/if:interfaces/if:interface" {
    when "if:type = 'ianaift:ieee8023adLag'";

    leaf-list slave-if {
      type if:interface-ref;
      must "/if:interfaces/if:interface[if:name = current()]"
        + "/if:type = 'ianaift:ethernetCsmacd'" {
        description
          "The type of a slave interface must be ethernet.";
      }
    }
  }
  leaf bonding-mode {
```

```
    type enumeration {
      enum round-robin;
      enum active-backup;
      enum broadcast;
    }
  }
  // other bonding config params, failover times etc.
}
}
```

### [Appendix C](#). Example: VLAN Interface Module

This section gives an example of how a vlan interface module can be defined.

---

```
module ex-vlan {
  namespace "http://example.com/vlan";
  prefix "vlan";

  import ietf-interfaces {
    prefix if;
  }
  import iana-if-type {
    prefix ianaift;
  }
  import ex-ethernet {
    prefix eth;
  }

  augment "/if:interfaces/if:interface" {
```

```

when "if:type = 'ianaift:ethernetCsmacd' or
     if:type = 'ianaift:ieee8023adLag'";
leaf vlan-tagging {
  type boolean;
  default false;
}
}

augment "/if:interfaces/if:interface" {
  when "if:type = 'ianaift:l2vlan'";

  leaf base-interface {
    type if:interface-ref;
    must "/if:interfaces/if:interface[if:name = current()]"
        + "/vlan:vlan-tagging = 'true'" {
      description
        "The base interface must have vlan tagging enabled.";
    }
  }
  leaf vlan-id {
    type uint16 {
      range "1..4094";
    }
    must "../base-interface" {
      description
        "If a vlan-id is defined, a base-interface must
        be specified.";
    }
  }
}
}
}

```

#### [Appendix D](#). Example: NETCONF <get> reply

This section gives an example of a reply to the NETCONF <get> request for a device that implements the example data models above.

## [Appendix E](#). Examples: Interface Naming Schemes

This section gives examples of some implementation strategies.

The examples make use of the example data model "ex-vlan" (see [Appendix C](#)) to show how user-controlled interfaces can be configured.

### [E.1](#). Router with Restricted Interface Names

In this example, a router has support for 4 line cards, each with 8 ports. The slots for the cards are physically numbered from 0 to 3, and the ports on each card from 0 to 7. Each card has fast- or gigabit-ethernet ports.

The device-specific names for these physical interfaces are "fastethernet-N/M" or "gigabitethernet-N/M".

The name of a vlan interface is restricted to the form "<physical-interface-name>.<subinterface-number>".

It is assumed that the operator is aware of this naming scheme. The implementation auto-initializes the value for "type" based on the interface name.

The NETCONF server does not advertise the 'arbitrary-names' feature in the <hello> message.

An operator can configure a physical interface by sending an <edit-config> containing:

```
<interface nc:operation="create">
  <name>fastethernet-1/0</name>
</interface>
```

When the server processes this request, it will set the leaf "type" to "ianaift:ethernetCsmacd". Thus, if the client performs a <get-config> right after the <edit-config> above, it will get:

```
<interface>
```

```
<name>fastethernet-1/0</name>
<type>ianaift:ethernetCsmacd</type>
</interface>
```

The client can configure a vlan interface by sending an `<edit-config>` containing:

```
<interface nc:operation="create">
  <name>fastethernet-1/0.10005</name>
  <type>ianaift:l2vlan</type>
  <vlan:base-interface>fastethernet-1/0</vlan:base-interface>
  <vlan:vlan-id>5</vlan:vlan-id>
</interface>
```

If the client tries to change the type of the physical interface with an `<edit-config>` containing:

```
<interface nc:operation="merge">
  <name>fastethernet-1/0</name>
  <type>ianaift:tunnel</type>
</interface>
```

then the server will reply with an "invalid-value" error, since the new type does not match the name.

## [E.2.](#) Router with Arbitrary Interface Names

In this example, a router has support for 4 line cards, each with 8 ports. The slots for the cards are physically numbered from 0 to 3, and the ports on each card from 0 to 7. Each card has fast- or gigabit-ethernet ports.

The device-specific names for these physical interfaces are "fastethernet-N/M" or "gigabitethernet-N/M".

The implementation does not restrict the user-controlled interface names. This allows to more easily apply the interface configuration to a different interface. However, the additional level of indirection also makes it a bit more complex to map interface names

found in other protocols to configuration entries.

The NETCONF server advertises the 'arbitrary-names' feature in the <hello> message.

Physical interfaces are configured as in [Appendix E.1](#).

An operator can configure a VLAN interface by sending an <edit-config> containing:

```
<interface nc:operation="create">
  <name>acme-interface</name>
  <type>ianaift:l2vlan</type>
  <vlan:base-interface>fastethernet-1/0</vlan:base-interface>
  <vlan:vlan-id>5</vlan:vlan-id>
</interface>
```

If necessary, the operator can move the configuration named "acme-interface" over to a different physical interface with an <edit-config> containing:

```
<interface nc:operation="merge">
  <name>acme-interface</name>
  <vlan:base-interface>fastethernet-1/1</vlan:base-interface>
</interface>
```

### [E.3](#). Ethernet Switch with Restricted Interface Names

In this example, an ethernet switch has a number of ports, each port identified by a simple port number.

The device-specific names for the physical interfaces are numbers that match the physical port number.

An operator can configure a physical interface by sending an <edit-config> containing:

```
<interface nc:operation="create">
  <name>6</name>
</interface>
```

When the server processes this request, it will set the leaf "type"

to "ianaift:ethernetCsmacd". Thus, if the client performs a <get-config> right after the <edit-config> above, it will get:

```
<interface>
  <name>6</name>
  <type>ianaift:ethernetCsmacd</type>
</interface>
```

#### [E.4.](#) Generic Host with Restricted Interface Names

In this example, a generic host has interfaces named by the kernel. The system identifies the physical interface by the name assigned by the operating system to the interface.

The name of a vlan interface is restricted to the form "<physical-interface-name>:<vlan-number>".

The NETCONF server does not advertise the 'arbitrary-names' feature in the <hello> message.

An operator can configure an interface by sending an <edit-config> containing:

```
<interface nc:operation="create">
  <name>eth8</name>
</interface>
```

When the server processes this request, it will set the leaf "type" to "ianaift:ethernetCsmacd". Thus, if the client performs a <get-config> right after the <edit-config> above, it will get:

```
<interface>
  <name>eth8</name>
  <type>ianaift:ethernetCsmacd</type>
</interface>
```

The client can configure a vlan interface by sending an <edit-config> containing:

```
<interface nc:operation="create">
  <name>eth8:5</name>
```

```
<type>ianaift:l2vlan</type>
<vlan:base-interface>eth8</vlan:base-interface>
<vlan:vlan-id>5</vlan:vlan-id>
</interface>
```

#### [E.5.](#) Generic Host with Arbitrary Interface Names

In this example, a generic host has interfaces named by the kernel. The system identifies the physical interface by the name assigned by the operating system to the interface.

The implementation does not restrict the user-controlled interface names. This allows to more easily apply the interface configuration to a different interface. However, the additional level of indirection also makes it a bit more complex to map interface names found in other protocols to configuration entries.

The NETCONF server advertises the 'arbitrary-names' feature in the <hello> message.

Physical interfaces are configured as in [Appendix E.4](#).

An operator can configure a VLAN interface by sending an <edit-config> containing:

```
<interface nc:operation="create">
  <name>acme-interface</name>
  <type>ianaift:l2vlan</type>
  <vlan:base-interface>eth8</vlan:base-interface>
  <vlan:vlan-id>5</vlan:vlan-id>
```

```
</interface>
```

If necessary, the operator can move the configuration named "acme-interface" over to a different physical interface with an <edit-config> containing:

```
<interface nc:operation="merge">
  <name>acme-interface</name>
  <vlan:base-interface>eth3</vlan:base-interface>
</interface>
```

[Appendix F](#). ChangeLog

RFC Editor: remove this section upon publication as an RFC.

#### [F.1.](#) Version -13

- o Made the interface type an identity, instead of an enumeration.

#### [F.2.](#) Version -11

- o Separated the operational state from the configuration.
- o Removed 'location', and instead use the name to identify physical interfaces.
- o Added the feature 'pre-provisioning'.
- o Made 'oper-status' and 'if-index' mandatory in the data model.
- o Added 'admin-status'.
- o Clarified why description can be mapped to ifAlias.
- o Clarified that 64-bit counters only are used, where there exist 64-bit and 32-bit counters in IF-MIB.
- o Updated Security Considerations section with a reference to NACM.

#### [F.3.](#) Version -08

- o Removed the mtu leaf.
- o Added examples of different interface naming schemes.

#### [F.4.](#) Version -07

- o Made leaf speed config false.

#### [F.5.](#) Version -06

- o Added oper-status leaf.
- o Added leaf-lists higher-layer-if and lower-layer-if, that show the interface layering.
- o Added container statistics with counters.

[F.6.](#) Version -05

- o Added an Informative References section.
- o Updated the Security Considerations section.
- o Clarified the behavior of an NETCONF server when invalid values are received.

[F.7.](#) Version -04

- o Clarified why ifPromiscuousMode is not part of this data model.
- o Added a table that shows the mapping between this YANG data model and IF-MIB.

[F.8.](#) Version -03

- o Added the section Relationship to the IF-MIB.
- o Changed if-index to be a leaf instead of leaf-list.
- o Explained the notation used in the data model tree picture.

[F.9.](#) Version -02

- o Editorial fixes

[F.10.](#) Version -01

- o Changed leaf "if-admin-status" to leaf "enabled".
- o Added Security Considerations
