**A YANG Data Model for Routing Management
draft-ietf-netmod-routing-cfg-10**

Abstract

This document contains a specification of three YANG modules. Together they form the core routing data model which serves as a framework for configuring and managing a routing subsystem. It is expected that these modules will be augmented by additional YANG modules defining data models for individual routing protocols and other related functions. The core routing data model provides common building blocks for such extensions - router instances, routes, routing tables, routing protocols and route filters.

Status of this Memo

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on January 14, 2014.

1. Introduction

This document contains a specification of the following YANG modules:

- o Module "ietf-routing" provides generic components of a routing data model.
- o Module "ietf-ipv4-unicast-routing" augments the "ietf-routing" module with additional data specific to IPv4 unicast.
- o Module "ietf-ipv6-unicast-routing" augments the "ietf-routing" module with additional data specific to IPv6 unicast, including the router configuration variables required by [[RFC4861](#)].

These modules together define the so-called core routing data model, which is proposed as a basis for the development of data models for configuration and management of more sophisticated routing systems. While these three modules can be directly used for simple IP devices with static routing, their main purpose is to provide essential building blocks for more complicated setups involving multiple routing protocols, multicast routing, additional address families, and advanced functions such as route filtering or policy routing. To this end, it is expected that the core routing data model will be augmented by numerous modules developed by other IETF working groups.

2. Terminology and Notation

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [[RFC2119](#)].

The following terms are defined in [[RFC6241](#)]:

- o client
- o message
- o protocol operation
- o server

The following terms are defined in [[RFC6020](#)]:

- o augment
- o configuration data
- o data model
- o data node
- o feature
- o mandatory node
- o module
- o state data
- o RPC operation

2.1. Glossary of New Terms

active route: a route that is actually used for sending packets. If there are multiple candidate routes with a matching destination prefix, then it is up to the routing algorithm to select the active route (or several active routes in the case of multi-path routing).

core routing data model: YANG data model resulting from the combination of "ietf-routing", "ietf-ipv4-unicast-routing" and "ietf-ipv6-unicast-routing" modules.

direct route: a route to a directly connected network.

system-controlled entry: An entry of a list in operational state data ("config false") that is created by the system independently of what has been explicitly configured. An example is the default routing table. A client cannot cause this entry to be deleted but may be able to configure it.

user-controlled entry: An entry of a list in operational state data ("config false") that is created and deleted as a direct consequence of certain configuration changes. An example is an additional user-defined routing table.

2.2. Tree Diagrams

A simplified graphical representation of the complete data tree is presented in [Appendix A](#), and similar diagrams of its various subtrees appear in the main text. The meaning of the symbols in these diagrams is as follows:

- o Brackets "[" and "]" enclose list keys.
- o Abbreviations before data node names: "rw" means configuration (read-write) and "ro" state data (read-only).
- o Symbols after data node names: "?" means an optional node and "*" denotes a "list" or "leaf-list".
- o Parentheses enclose choice and case nodes, and case nodes are also marked with a colon (":").
- o Ellipsis ("...") stands for contents of subtrees that are not shown.

2.3. Prefixes in Data Node Names

In this document, names of data nodes, RPC methods and other data model objects are used mostly without a prefix, as long as it is clear from the context in which YANG module each name is defined. Otherwise, names are prefixed using the standard prefix associated with the corresponding YANG module, as shown in Table 1.

Prefix	YANG module	Reference
ianaaf	iana-afn-safi	[IANA-AF]
if	ietf-interfaces	[YANG-IF]
ip	ietf-ip	[YANG-IP]
rt	ietf-routing	Section 6
v4ur	ietf-ipv4-unicast-routing	Section 7
v6ur	ietf-ipv6-unicast-routing	Section 8
yang	ietf-yang-types	[RFC6021bis]
inet	ietf-inet-types	[RFC6021bis]

Table 1: Prefixes and corresponding YANG modules

3. Objectives

The initial design of the core routing data model was driven by the following objectives:

- o The data model should be suitable for the common address families, in particular IPv4 and IPv6, and for unicast and multicast routing, as well as Multiprotocol Label Switching (MPLS).
- o Simple routing setups, such as static routing, should be configurable in a simple way, ideally without any need to develop additional YANG modules.
- o On the other hand, the core routing framework must allow for complicated setups involving multiple routing tables and multiple routing protocols, as well as controlled redistributions of routing information.
- o Device vendors will want to map the data models built on this generic framework to their proprietary data models and configuration interfaces. Therefore, the framework should be flexible enough to facilitate such a mapping and accommodate data models with different logic.

4. The Design of the Core Routing Data Model

The core routing data model consists of three YANG modules. The first module, "ietf-routing", defines the generic components of a routing system. The other two modules, "ietf-ipv4-unicast-routing" and "ietf-ipv6-unicast-routing", augment the "ietf-routing" module with additional data nodes that are needed for IPv4 and IPv6 unicast routing, respectively. Figures 1 and 2 show abridged views of the configuration and operational state data hierarchies. See [Appendix A](#) for the complete data trees.

Figure 2: Operational state data hierarchy.

As can be seen from Figures 1 and 2, the core routing data model introduces several generic components of a routing framework: routers, routing tables containing lists of routes, routing protocols and route filters. The following subsections describe these components in more detail.

By combining the components in various ways, and possibly augmenting them with appropriate contents defined in other modules, various routing systems can be realized.

Lhotka

[Page 11]

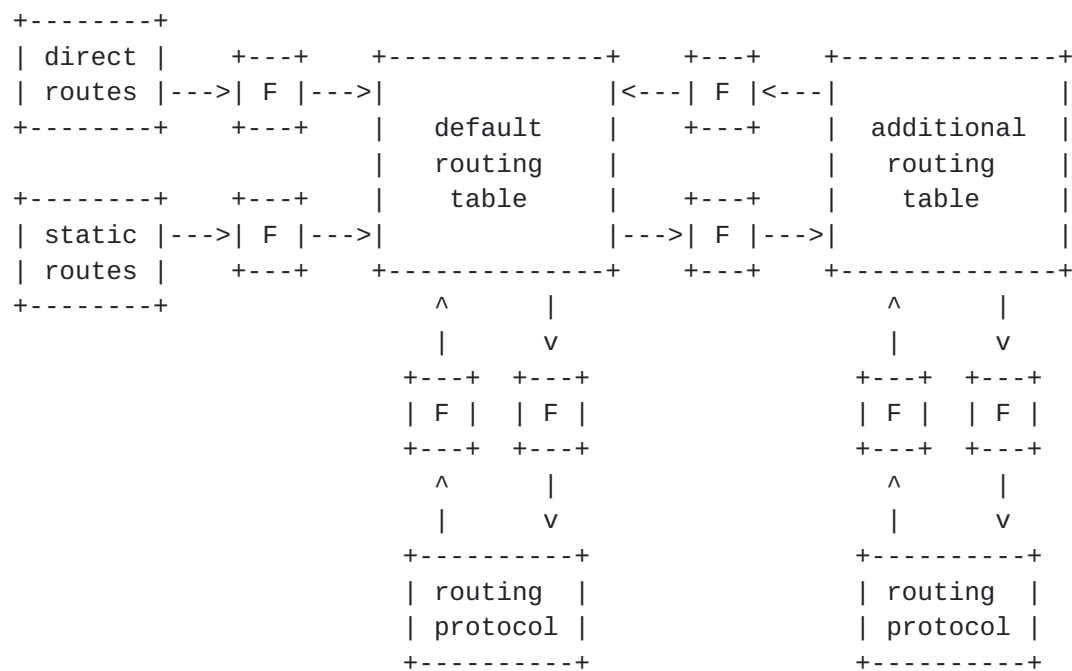

Figure 3: Example setup of a routing system

The example in Figure 3 shows a typical (though certainly not the only possible) organization of a more complex routing subsystem for a single address family. Several of its features are worth mentioning:

- o Along with the default routing table, which is always present, an additional routing table is configured.
- o Each routing protocol instance, including the "static" and "direct" pseudo-protocols, is connected to one routing table with which it can exchange routes (in both directions, except for the "static" and "direct" pseudo-protocols).
- o Routing tables may also be connected to each other and exchange routes in either direction (or both).
- o Route exchanges along all connections may be controlled by means of route filters, denoted by "F" in Figure 3.

4.1. Router

Each router instance in the core routing data model represents a logical router. The exact semantics of this term is left to implementations. For example, router instances may be completely isolated virtual routers or, alternatively, they may internally share certain information.

Lhotka

Expires January 14, 2014

[Page 12]

A router instance together with its operational status is represented as an entry of the list `"/routing-state/router"`, and identified by a unique name. Configuration of that router instance appears as entry of the list `"/routing/router"` whose key is the router instance name.

An implementation MAY support multiple types of logical routers simultaneously. Instances of all router types are organized as entries of the same flat `"router"` list. In order to discriminate router instances belonging to different types, the `"type"` leaf is defined as a child of the `"router"` node.

An implementation MAY create one or more system-controlled router entries, and MAY also pose restrictions on allowed router types and on the number of supported instances for each type. For example, a simple router implementation may support only one system-controlled router instance of the default type `"standard-router"` and may not allow creation of any user-controlled instances.

Each network layer interface has to be assigned to one or more router instances in order to be able to participate in packet forwarding, routing protocols and other operations of those router instances. The assignment is accomplished by creating a corresponding entry in the list of router interfaces (`"rt:interface"`). The key of the list entry is the name of a configured network layer interface, see the `"ietf-interfaces"` module [[YANG-IF](#)].

In YANG terms, the list of router interfaces is modeled as the `"list"` node rather than `"leaf-list"` in order to allow for adding, via augmentation, other configuration or state data related to the corresponding router interface.

Implementations MAY specify additional rules for the assignment of interfaces to logical routers. For example, it may be required that the sets of interfaces assigned to different logical routers be disjoint.

4.1.1.1. Parameters of IPv6 Router Interfaces

The module `"ietf-ipv6-unicast-routing"` augments the definition of the data node `"rt:interface"`, in both configuration and operational state data, with definitions of the following variables as required by [[RFC4861](#)], sec. 6.2.1:

- o `send-advertisements`,
- o `max-rtr-adv-interval`,

- o min-rtr-adv-interval,
- o managed-flag,
- o other-config-flag,
- o link-mtu,
- o reachable-time,
- o retrans-timer,
- o cur-hop-limit,
- o default-lifetime,
- o prefix-list: a list of prefixes to be advertised.

The following parameters are associated with each prefix in the list:

- * valid-lifetime,
- * on-link-flag,
- * preferred-lifetime,
- * autonomous-flag.

The definitions and descriptions of the above parameters can be found in the text of the module "ietf-ipv6-unicast-routing" ([Section 8](#)).

NOTES:

1. The "IsRouter" flag, which is also required by [\[RFC4861\]](#), is implemented in the "ietf-ip" module [\[YANG-IP\]](#) (leaf "ip:forwarding").
2. The original specification [\[RFC4861\]](#) allows the implementations to decide whether the "valid-lifetime" and "preferred-lifetime" parameters remain the same in consecutive advertisements, or decrement in real time. However, the latter behavior seems problematic because the values might be reset again to the (higher) configured values after a configuration is reloaded. Moreover, no implementation is known to use the decrementing behavior. The "ietf-ipv6-unicast-routing" module therefore assumes the former behavior with constant values.

4.2. Routes

Routes are basic elements of information in a routing system. The core routing data model defines only the following minimal set of route attributes:

- o "dest-prefix": IP prefix specifying the set of destination addresses for which the route may be used. This attribute is mandatory.
- o "next-hop": IP address of an adjacent router or host to which packets with destination addresses belonging to "dest-prefix" should be sent.
- o "outgoing-interface": network interface that should be used for sending packets with destination addresses belonging to "dest-prefix".

The above list of route attributes suffices for a simple static routing configuration. It is expected that future modules defining routing protocols will add other route attributes such as metrics or preferences.

Routes and their attributes are used both in configuration data, for example as manually configured static routes, and in operational state data, for example as entries in routing tables.

4.3. Routing Tables

Routing tables are lists of routes complemented with administrative data, namely:

- o "source-protocol": type of the routing protocol from which the route was originally obtained.
- o "last-updated": the date and time when the route was last updated, or inserted into the routing table.

Each routing table must contain only routes of the same address family. Address family information consists of two parameters - "address-family" and "safi" (Subsequent Address Family Identifier, SAFI). The permitted values for these two parameters are defined by IANA and represented using YANG enumeration datatypes "ianaaf:address-family" and "ianaaf:subsequent-address-family" [[IANA-AF](#)].

In the core routing data model, routing tables are operational state data represented as entries of the list `"/routing-state/routing-tables/routing-table"`. The contents of routing tables are

controlled and manipulated by routing protocol operations which may result in route additions, removals and modifications. This also includes manipulations via the "static" and/or "direct" pseudo-protocols, see [Section 4.4.1](#).

Routing tables are global, which means that a routing table may be used by any or all router instances. However, an implementation MAY specify rules and restrictions for sharing routing tables among router instances.

Each router instance must have, for every supported address family, one routing table selected as the so-called default routing table. This selection is recorded in the list "default-routing-table". The role of default routing tables is explained in [Section 4.4](#).

Simple router implementations will typically create one system-controlled routing table per supported address family, and declare it as a default routing table (via a system-controlled entry of the "default-routing-table" list).

[4.3.1](#). User-Defined Routing Tables

More complex router implementations allow for multiple routing tables per address family that are used for policy routing and other purposes. If it is the case, the NETCONF server SHALL advertise the feature "user-defined-routing-tables". This feature activates additional nodes in both configuration and operational state data, and enables the client to:

- o Configure new user-controlled routing tables by creating entries in the "/routing/routing-tables/routing-table" list.
- o Configure any (system-controlled or user-controlled) routing table as the default routing table for an address family.
- o Connect a routing protocol instance to a non-default routing table (see [Section 4.4](#)).
- o Configure a routing table as a recipient routing table of another routing table (see below).

Every routing table can serve as a source of routes for other routing tables of the same address family. To achieve this, one or more recipient routing tables may be specified in the configuration of the source routing table. Optionally, a route filter may be configured for any or all recipient routing tables. Such a route filter then selects and/or manipulates the routes that are passed between the source and recipient routing table.

A routing table MUST NOT appear among its own recipient routing tables.

4.4. Routing Protocols

The core routing data model provides an open-ended framework for defining multiple routing protocol instances within a router instance. Each routing protocol instance MUST be assigned a type, which is an identity derived from the "rt:routing-protocol" base identity. The core routing data model defines two identities for the direct and static pseudo-protocols ([Section 4.4.1](#)).

Each routing protocol instance is connected to exactly one routing table for each address family that the routing protocol instance supports. Routes learned from the network by a routing protocol are normally installed into the connected routing table(s) and, conversely, routes from the connected routing table(s) are normally injected into the routing protocol. However, routing protocol implementations MAY specify rules that restrict this exchange of routes in either direction (or both directions).

On devices supporting the "user-defined-routing-tables" feature, a routing table (system-controlled or user-controlled) is connected to a routing protocol instance by configuring a corresponding entry in the "connected-routing-table" list. If such an entry is not configured for an address family, then the default routing table MUST be used as the connected routing table for this address family.

In addition, two independent route filters (see [Section 4.5](#)) may be configured for each connected routing table to apply client-defined policies controlling the exchange of routes in both directions between the routing protocol instance and the connected routing table:

- o import filter controls which routes are passed from the routing protocol instance to the connected routing table,
- o export filter controls which routes the routing protocol instance receives from the connected routing table.

Note that the terms import and export are used from the viewpoint of a routing table.

4.4.1. Routing Pseudo-Protocols

The core routing data model defines two special routing protocol types - "direct" and "static". Both are in fact pseudo-protocols, which means that they are confined to the local device and do not

exchange any routing information with neighboring routers. Routes from both "direct" and "static" protocol instances are passed to the connected routing table (subject to route filters, if any), but an exchange in the opposite direction is not allowed.

Every router instance MUST implement exactly one instance of the "direct" pseudo-protocol type. The name of this instance MUST also be "direct". It is the source of direct routes for all configured address families. Direct routes are normally supplied by the operating system kernel, based on the configuration of network interface addresses, see [Section 5.2](#). The "direct" pseudo-protocol MUST always be connected to the default routing tables of all supported address families. Unlike other routing protocol types, this connection cannot be changed in the configuration. Direct routes MAY be filtered before they appear in the default routing table.

A pseudo-protocol of the type "static" allows for specifying routes manually. It MAY be configured in zero or multiple instances, although a typical configuration will have exactly one instance per logical router.

Static routes are configured within the "static-routes" container, see Figure 4.

```
+--rw static-routes
  +--rw v4ur:ipv4
    | +--rw v4ur:route* [id]
    |   +--rw v4ur:id
    |   +--rw v4ur:description?
    |   +--rw v4ur:outgoing-interface?
    |   +--rw v4ur:dest-prefix
    |   +--rw v4ur:next-hop?
  +--rw v6ur:ipv6
    +--rw v6ur:route* [id]
      +--rw v6ur:id
      +--rw v6ur:description?
      +--rw v6ur:outgoing-interface?
      +--rw v6ur:dest-prefix
      +--rw v6ur:next-hop?
```

Figure 4: Structure of "static-routes" subtree.

[4.4.2](#). Defining New Routing Protocols

It is expected that future YANG modules will create data models for additional routing protocol types. Such a new module has to define the protocol-specific configuration and state data, and it has to fit

it into the core routing framework in the following way:

- o A new identity **MUST** be defined for the routing protocol and its base identity **MUST** be set to "rt:routing-protocol", or to an identity derived from "rt:routing-protocol".
- o Additional route attributes **MAY** be defined, preferably in one place by means of defining a YANG grouping. The new attributes have to be inserted as state data by augmenting the definitions of the nodes

/rt:routing-tables/rt:routing-table/rt:route

and

/rt:active-route/rt:output/rt:route,

and possibly other places in the configuration, state data and RPC input or output.

- o Configuration parameters and/or state data for the new protocol can be defined by augmenting the "routing-protocol" data node under both "/routing" and "/routing-state".
- o Per-interface configuration, including activation of the routing protocol on individual interfaces, can use references to entries in the list of router interfaces (rt:interface).

By using the "when" statement, the augmented configuration parameters and state data specific to the new protocol **SHOULD** be made conditional and valid only if the value of "rt:type" or "rt:source-protocol" is equal to the new protocol's identity. It is also **RECOMMENDED** that the protocol-specific data be encapsulated in appropriately named containers.

The above steps are implemented by the example YANG module for the RIP routing protocol in [Appendix B](#).

4.5. Route Filters

The core routing data model provides a skeleton for defining route filters that can be used to restrict the set of routes being exchanged between a routing protocol instance and a connected routing table, or between a source and a recipient routing table. Route filters may also manipulate routes, i.e., add, delete, or modify their attributes.

Route filters are global, which means that a configured route filter

may be used by any or all router instances. However, an implementation MAY specify rules and restrictions for sharing route filters among router instances.

By itself, the route filtering framework defined in this document allows for applying only two extreme routing policies which are represented by the following pre-defined route filter types:

- o "deny-all-route-filter": all routes are blocked,
- o "allow-all-route-filter": all routes are permitted.

The latter type is equivalent to no route filter.

It is expected that more comprehensive route filtering frameworks will be developed separately.

Each route filter is identified by a unique name. Its type MUST be specified by the "type" identity reference - this opens the space for multiple route filtering framework implementations.

4.6. RPC Operations

The "ietf-routing" module defines two RPC operations:

- o active-route: query the routing system for the active route(s) that are currently used for sending datagrams to a destination host whose address is passed as an input parameter.
- o route-count: retrieve the total number of entries in a routing table.

5. Interactions with Other YANG Modules

The semantics of the core routing data model also depend on several configuration parameters that are defined in other YANG modules.

5.1. Module "ietf-interfaces"

The following boolean switch is defined in the "ietf-interfaces" YANG module [[YANG-IF](#)]:

```
/if:interfaces/if:interface/if:enabled
```

If this switch is set to "false" for a given network layer interface, the device **MUST** behave exactly as if that interface was not assigned to any logical router at all.

5.2. Module "ietf-ip"

The following boolean switches are defined in the "ietf-ip" YANG module [[YANG-IP](#)]:

```
/if:interfaces/if:interface/ip:ipv4/ip:enabled
```

If this switch is set to "false" for a given interface, then all IPv4 routing functions related to that interface **MUST** be disabled.

```
/if:interfaces/if:interface/ip:ipv4/ip:forwarding
```

If this switch is set to "false" for a given interface, then the forwarding of IPv4 datagrams to and from this interface **MUST** be disabled. However, the interface may participate in other routing functions, such as routing protocols.

```
/if:interfaces/if:interface/ip:ipv6/ip:enabled
```

If this switch is set to "false" for a given interface, then all IPv6 routing functions related to that interface **MUST** be disabled.

```
/if:interfaces/if:interface/ip:ipv6/ip:forwarding
```

If this switch is set to "false" for a given interface, then the forwarding of IPv6 datagrams to and from this interface **MUST** be disabled. However, the interface may participate in other routing functions, such as routing protocols.

In addition, the "ietf-ip" module allows for configuring IPv4 and IPv6 addresses and network prefixes or masks on network layer interfaces. Configuration of these parameters on an enabled

interface MUST result in an immediate creation of the corresponding direct route. The destination prefix of this route is set according to the configured IP address and network prefix/mask, and the interface is set as the outgoing interface for that route.

6. Routing YANG Module

RFC Ed.: In this section, replace all occurrences of 'XXXX' with the actual RFC number and all occurrences of the revision date below with the date of RFC publication (and remove this note).

9. IANA Considerations

RFC Ed.: In this section, replace all occurrences of 'XXXX' with the actual RFC number (and remove this note).

This document registers the following namespace URIs in the IETF XML registry [[RFC3688](#)]:

URI: urn:ietf:params:xml:ns:yang:ietf-routing

Registrant Contact: The IESG.

XML: N/A, the requested URI is an XML namespace.

URI: urn:ietf:params:xml:ns:yang:ietf-ipv4-unicast-routing

Registrant Contact: The IESG.

XML: N/A, the requested URI is an XML namespace.

URI: urn:ietf:params:xml:ns:yang:ietf-ipv6-unicast-routing

Registrant Contact: The IESG.

XML: N/A, the requested URI is an XML namespace.

This document registers the following YANG modules in the YANG Module Names registry [[RFC6020](#)]:

```
-----  
name:          ietf-routing  
namespace:     urn:ietf:params:xml:ns:yang:ietf-routing  
prefix:        rt  
reference:     RFC XXXX  
-----
```

```
-----  
name:          ietf-ipv4-unicast-routing  
namespace:     urn:ietf:params:xml:ns:yang:ietf-ipv4-unicast-routing  
prefix:        v4ur  
reference:     RFC XXXX  
-----
```

```
-----  
name:          ietf-ipv6-unicast-routing  
namespace:     urn:ietf:params:xml:ns:yang:ietf-ipv6-unicast-routing  
prefix:        v6ur  
reference:     RFC XXXX  
-----
```

10. Security Considerations

Configuration and state data conforming to the core routing data model (defined in this document) are designed to be accessed via the NETCONF protocol [[RFC6241](#)]. The lowest NETCONF layer is the secure transport layer and the mandatory-to-implement secure transport is SSH [[RFC6242](#)].

A number of data nodes defined in the YANG modules belonging to the configuration part of the core routing data model are writable/creatable/deletable (i.e., "config true" in YANG terms, which is the default). These data nodes may be considered sensitive or vulnerable in some network environments. Write operations to these data nodes, such as "edit-config", can have negative effects on the network if the protocol operations are not properly protected.

The vulnerable "config true" subtrees and data nodes are the following:

`/routing/router/interfaces/interface` This list assigns a network layer interface to a router instance and may also specify interface parameters related to routing.

`/routing/router/routing-protocols/routing-protocol` This list specifies the routing protocols configured on a device.

`/routing/route-filters/route-filter` This list specifies the configured route filters which represent administrative policies for redistributing and modifying routing information.

`/routing/routing-tables/routing-table` This list specifies the configured routing tables used by the device.

Unauthorized access to any of these lists can adversely affect the routing subsystem of both the local device and the network. This may lead to network malfunctions, delivery of packets to inappropriate destinations and other problems.

11. Acknowledgments

The author wishes to thank Martin Bjorklund, Joel Halpern, Wes Hardaker, Andrew McGregor, Xiang Li, Thomas Morin, Tom Petch, Bruno Rijsman, Juergen Schoenwaelder, Phil Shafer, Dave Thaler and Yi Yang for their helpful comments and suggestions.

Appendix A. The Complete Data Trees

This appendix presents the complete configuration and operational state data trees of the core routing data model.

See [Section 2.2](#) for an explanation of the symbols used. Data type of every leaf node is shown near the right end of the corresponding line.

[Appendix B](#). Example: Adding a New Routing Protocol

This appendix demonstrates how the core routing data model can be extended to support a new routing protocol. The YANG module "example-rip" shown below is intended only as an illustration rather than a real definition of a data model for the RIP routing protocol. For the sake of brevity, we do not follow all the guidelines specified in [\[RFC6087\]](#). See also [Section 4.4.2](#).

```
module example-rip {  
  
    namespace "http://example.com/rip";  
  
    prefix "rip";  
  
    import ietf-routing {  
        prefix "rt";  
    }  
  
    identity rip {  
        base rt:routing-protocol;  
        description  
            "Identity for the RIP routing protocol.";  
    }  
  
    typedef rip-metric {  
        type uint8 {  
            range "0..16";  
        }  
    }  
  
    grouping route-content {  
        description  
            "This grouping defines RIP-specific route attributes.";  
        leaf metric {  
            type rip-metric;  
        }  
        leaf tag {  
            type uint16;  
            default "0";  
            description  
                "This leaf may be used to carry additional info, e.g. AS  
                number.";  
        }  
    }  
  
    augment "/rt:routing-state/rt:routing-tables/rt:routing-table/"  
        + "rt:routes/rt:route" {  

```

Lhotka

  when "rt:type = 'rip:rip'" {
    description
      "This augment is only valid for a routing protocol instance
      of type 'rip'.";
  }
  container rip {
    description
      "RIP instance configuration.";
    container interfaces {
      description
        "Per-interface RIP configuration.";
      list interface {
        key "name";
        description
          "RIP is enabled on interfaces that have an entry in this
          list, unless 'enabled' is set to 'false' for that
          entry.";
        leaf name {
          type leafref {
            path "../.../rt:interfaces/rt:interface/"
              + "rt:name";
          }
        }
        leaf enabled {
          type boolean;
          default "true";
        }
        leaf metric {
          type rip-metric;
        }
      }
    }
  }
}
```

    }
}
leaf update-interval {
    type uint8 {
        range "10..60";
    }
    units "seconds";
    default "30";
    description
        "Time interval between periodic updates.";
}
}
}
```

Appendix C. Example: NETCONF <get> Reply

This section contains a sample reply to the NETCONF <get> message, which could be sent by a server supporting (i.e., advertising them in the NETCONF <hello> message) the following YANG modules:

- o ietf-interfaces [[YANG-IF](#)],
- o ietf-ip [[YANG-IP](#)],
- o ietf-routing ([Section 6](#)),
- o ietf-ipv4-unicast-routing ([Section 7](#)),
- o ietf-ipv6-unicast-routing ([Section 8](#)).

We assume a simple network setup as shown in Figure 5: router "A" uses static default routes with the "ISP" router as the next hop. IPv6 router advertisements are configured only on the "eth1" interface and disabled on the upstream "eth0" interface.

Figure 5: Example network configuration

A reply to the NETCONF <get> message sent by router "A" would then be as follows:

```

<?xml version="1.0"?>
<rpc-reply

```

```
message-id="101"
xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"

Appendix D. Change Log

RFC Editor: remove this section upon publication as an RFC.

D.1. Changes Between Versions -09 and -10

- o Added subtree for operational state data ("/routing-state").
- o Terms "system-controlled entry" and "user-controlled entry" defined and used.
- o New feature "user-defined-routing-tables". Nodes that are useful only with user-defined routing tables are now conditional.
- o Added grouping "router-id".
- o In routing tables, "source-protocol" attribute of routes now reports only protocol type, and its datatype is "identityref".
- o Renamed "main-routing-table" to "default-routing-table".

D.2. Changes Between Versions -08 and -09

- o Fixed "must" expresion for "connected-routing-table".
- o Simplified "must" expression for "main-routing-table".
- o Moved per-interface configuration of a new routing protocol under 'routing-protocol'. This also affects the 'example-rip' module.

D.3. Changes Between Versions -07 and -08

- o Changed reference from [RFC6021](#) to RFC6021bis.

D.4. Changes Between Versions -06 and -07

- o The contents of <get-reply> in [Appendix C](#) was updated: "eth[01]" is used as the value of "location", and "forwarding" is on for both interfaces and both IPv4 and IPv6.
- o The "must" expression for "main-routing-table" was modified to avoid redundant error messages reporting address family mismatch when "name" points to a non-existent routing table.
- o The default behavior for IPv6 RA prefix advertisements was clarified.

- o Changed type of "rt:router-id" to "ip:dotted-quad".
- o Type of "rt:router-id" changed to "yang:dotted-quad".
- o Fixed missing prefixes in XPath expressions.

D.5. Changes Between Versions -05 and -06

- o Document title changed: "Configuration" was replaced by "Management".
- o New typedefs "routing-table-ref" and "route-filter-ref".
- o Double slashes "/" were removed from XPath expressions and replaced with the single "/".
- o Removed uniqueness requirement for "router-id".
- o Complete data tree is now in [Appendix A](#).
- o Changed type of "source-protocol" from "leafref" to "string".
- o Clarified the relationship between routing protocol instances and connected routing tables.
- o Added a must constraint saying that a routing table connected to the direct pseudo-protocol must not be a main routing table.

D.6. Changes Between Versions -04 and -05

- o Routing tables are now global, i.e., "routing-tables" is a child of "routing" rather than "router".
- o "must" statement for "static-routes" changed to "when".
- o Added "main-routing-tables" containing references to main routing tables for each address family.
- o Removed the defaults for "address-family" and "safi" and made them mandatory.
- o Removed the default for route-filter/type and made this leaf mandatory.
- o If there is no active route for a given destination, the "active-route" RPC returns no output.

- o Added "enabled" switch under "routing-protocol".
- o Added "router-type" identity and "type" leaf under "router".
- o Route attribute "age" changed to "last-updated", its type is "yang:date-and-time".
- o The "direct" pseudo-protocol is always connected to main routing tables.
- o Entries in the list of connected routing tables renamed from "routing-table" to "connected-routing-table".
- o Added "must" constraint saying that a routing table must not be its own recipient.

D.7. Changes Between Versions -03 and -04

- o Changed "error-tag" for both RPC methods from "missing element" to "data-missing".
- o Removed the decrementing behavior for advertised IPv6 prefix parameters "valid-lifetime" and "preferred-lifetime".
- o Changed the key of the static route lists from "seqno" to "id" because the routes needn't be sorted.
- o Added 'must' constraint saying that "preferred-lifetime" must not be greater than "valid-lifetime".

D.8. Changes Between Versions -02 and -03

- o Module "iana-afn-safi" moved to I-D "iana-if-type".
- o Removed forwarding table.
- o RPC "get-route" changed to "active-route". Its output is a list of routes (for multi-path routing).
- o New RPC "route-count".
- o For both RPCs, specification of negative responses was added.
- o Relaxed separation of router instances.
- o Assignment of interfaces to router instances needn't be disjoint.

- o Route filters are now global.
- o Added "allow-all-route-filter" for symmetry.
- o Added [Section 5](#) about interactions with "ietf-interfaces" and "ietf-ip".
- o Added "router-id" leaf.
- o Specified the names for IPv4/IPv6 unicast main routing tables.
- o Route parameter "last-modified" changed to "age".
- o Added container "recipient-routing-tables".

[D.9.](#) Changes Between Versions -01 and -02

- o Added module "ietf-ipv6-unicast-routing".
- o The example in [Appendix C](#) now uses IP addresses from blocks reserved for documentation.
- o Direct routes appear by default in the forwarding table.
- o Network layer interfaces must be assigned to a router instance. Additional interface configuration may be present.
- o The "when" statement is only used with "augment", "must" is used elsewhere.
- o Additional "must" statements were added.
- o The "route-content" grouping for IPv4 and IPv6 unicast now includes the material from the "ietf-routing" version via "uses rt:route-content".
- o Explanation of symbols in the tree representation of data model hierarchy.

[D.10.](#) Changes Between Versions -00 and -01

- o AFN/SAFI-independent stuff was moved to the "ietf-routing" module.
- o Typedefs for AFN and SAFI were placed in a separate "iana-afn-safi" module.
- o Names of some data nodes were changed, in particular "routing-process" is now "router".

- o The restriction of a single AFN/SAFI per router was lifted.
- o RPC operation "delete-route" was removed.
- o Illegal XPath references from "get-route" to the datastore were fixed.
- o Section "Security Considerations" was written.
