YANG Instance Data File Format  
draft-ietf-netmod-yang-instance-file-format-07

## Abstract

There is a need to document data defined in YANG models when a live server is not available. Data is often needed already at design or implementation time or needed by groups that do not have a live running server available. This document specifies a standard file format for YANG instance data, which follows the syntax and semantics of existing YANG models, and annotates it with metadata.

## Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <https://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on August 16, 2020.

## [1.](#) Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [BCP](#)

[14 RFC 2119](#) [[RFC2119](#)] [RFC 8174](#) [[RFC8174](#)] when, and only when, they appear in all capitals, as shown here.

Instance Data: A collection of instantiated data nodes.

**Instance Data Set:** A named set of data items annotated with metadata that can be used as instance data in a YANG data tree.

**Instance Data File:** A file containing an instance data set formatted according to the rules described in this document.

**Content-schema:** A set of YANG modules with their revision, supported features, and deviations for which the instance data set contains instance data.

**Content defining YANG module:** an individual YANG module that is part of the content-schema.

The term Server is used as defined in [[RFC8342](#)].

## [2.](#) Introduction

There is a need to document data defined in YANG models when a live server is not available. Data is often needed already at design or implementation time or needed by groups that do not have a live running server available. To facilitate this offline delivery of data, this document specifies a standard format for YANG instance data sets and YANG instance data files.

The following is a list of already implemented and potential use cases.

UC1 Documentation of server capabilities

UC2 Preloading default configuration data

UC3 Documenting Factory Default Settings

UC4 Storing the configuration of a device, e.g., for backup, archive or audit purposes

UC5 Storing diagnostics data

UC6 Allowing YANG instance data to potentially be carried within other IPC message formats

UC7 Default instance data used as part of a templating solution

UC8 Providing data examples in RFCs or internet drafts

In [Appendix C](#) we describe the first three use cases in detail.

There are many and varied use cases where YANG instance data could be used. We do not want to limit future uses of instance data sets, so specifying how and when to use YANG instance data is out of scope for this document. It is anticipated that other documents will define specific use cases. Use cases are listed here only to indicate the need for this work.

## [2.1.](#) Principles

The following is a list of the basic principles of the instance data format:

- P1 Two standard formats shall be defined based on the XML and JSON encodings.
- P2 Instance data shall reuse existing encoding rules for YANG defined data. Its format will be similar to the response of a NETCONF <get> operation or the RESTCONF response to a GET method invocation on the (unified) datastore resource.
- P3 Metadata about the instance data set ([Section 3](#), Paragraph 9) shall be defined.
- P4 A YANG instance data set shall be allowed to contain data for multiple YANG modules.
- P5 Instance data shall be allowed to contain configuration data, state data, or a mix of the two.

P6 Partial data sets shall be allowed.

P7 The YANG instance data format shall be usable for any data for which YANG module(s) are defined and available to the reader, independent of whether the module is actually implemented by a server.

## [2.2.](#) Delivery of Instance Data

Instance data sets that are produced as a result of some sort of specification or design effort may be available without the need for a live server e.g., via download from the vendor's website, or in any other way that product documentation is distributed.

Other instance data sets may be read from or produced by the YANG server itself e.g., UC5 documenting diagnostic data.

## [2.3.](#) Data Life cycle

YANG instance data is always a snapshot of information at a specific point of time. If the data changes afterwards, this is not represented in the instance data set anymore. The current values may be retrieved at run-time via NETCONF/RESTCONF or received e.g., in YANG-Push notifications.

Whether the instance data changes and if so, when and how, should be described either in the instance data set's description statement or in some other implementation specific manner.

## [3.](#) Instance Data File Format

A YANG instance data file MUST contain a single instance data set and no additional data.

The format of the instance data set is defined by the ietf-yang-instance-data YANG module. It is made up of a header part and content-data. The header part carries metadata for the instance data set. The content-data, defined as an anydata data node, carries the instance data that we want to document/provide. The syntax and

semantics of content-data is defined by the content-schema.

Two formats are specified based on the XML and JSON YANG encodings. Later as other YANG encodings (e.g., CBOR) are defined, further instance data formats may be specified.

The content-data part MUST conform to the content-schema, while allowing for the exceptions listed below. The content-data part SHALL follow the encoding rules defined in [\[RFC7950\]](#) for XML and [\[RFC7951\]](#) for JSON and MUST use UTF-8 character encoding. Content-data MAY include:

metadata as defined by [\[RFC7952\]](#).

a default attribute as defined in [\[RFC6243\] section 6.](#) and in [\[RFC8040\] section 4.8.9.](#)

origin metadata as specified in [\[RFC8526\]](#) and [\[RFC8527\]](#)

implementation specific metadata relevant to individual data nodes. Unknown metadata MUST be ignored by users of instance data, allowing it to be used later for other purposes.

in the XML format implementation specific XML attributes, unknown attributes MUST be ignored by users of instance data, allowing them to be used later for other purposes.

An instance data set MAY contain data for any number of YANG modules; if needed it MAY carry the complete configuration and state data set for a server. Default values SHOULD NOT be included.

Config=true and config=false data MAY be mixed in the instance data file.

Instance data files MAY contain partial data sets. This means mandatory, min-elements, require-instance=true, must and when constrains MAY be violated.

The name of the instance data file SHOULD take one of the following two forms:

If revision information inside the data set is present

\* instance-data-set-name ['@' revision-date] '.filetype'

\* E.g., acme-router-modules@2018-01-25.xml

If the leaf "name" is present in the instance data header, this MUST be used. If the "revision-date" is present in both the filename and in the instance data header, the revision date in the file name MUST be set to the latest revision date inside the instance data set.

If timestamp information inside the data set is present

\* instance-data-set-name ['@' timestamp] '.filetype'

\* E.g., acme-router-modules@2018-01-25T15\_06\_34\_3+01\_00.json

If the leaf "name" is present in the instance data header, this MUST be used. If the "timestamp" is present both in the filename and in the instance data header, the timestamp in the file name MUST be set to the timestamp inside the instance data set; the semicolons and the decimal point, if present, shall be replaced by underscores.

The revision date or timestamp is optional. ".filetype" SHALL be ".json" or ".xml" according to the format used.

Metadata, information about the data set itself SHOULD be included in the instance data set. Some metadata items are defined in the YANG module ietf-yang-instance-data, but other items MAY also be used. Metadata MUST include:

Version of the YANG Instance Data format

Metadata SHOULD include:

- o Name of the data set
- o Content schema specification
- o Description of the instance data set. The description SHOULD contain information whether and how the data can change during the

lifetime of the server.

### [3.1.](#) Specifying the Content Schema

To properly understand and use an instance data set, the user needs to know the content-schema. One of the following methods SHOULD be used:

Inline method: Include the needed information as part of the instance data set.

Simplified-Inline method: Include the needed information as part of the instance data set; short specification.

URI method: Include a URI that references another YANG instance data file. This instance data file will use the same content-schema as the referenced YANG instance data file. (if you don't want to repeat the info again and again)

External Method: Do not include the content-schema, the user needs to obtain the information through external documents.

Additional methods e.g., a YANG-package based solution may be added later.

Note, the specified content-schema only indicates the set of modules that were used to define this YANG instance data set. Sometimes instance data may be used for a server supporting a different YANG module set. (e.g., for "UC2 Preloading Data" the instance data set may not be updated every time the YANG modules on the server are updated) Whether an instance data set originally defined using a specific content-schema is usable with a different other schema depends on many factors including the amount of differences and the compatibility between the original and the other schema, considering modules, revisions, features, deviations, the scope of the instance data, etc.

#### [3.1.1.](#) Inline Method

One or more `inline-module` elements define YANG module(s) used to specify the content defining YANG modules.

E.g., `ietf-yang-library@2016-06-21`

The `anydata inline-schema` carries instance data (conforming to the `inline-modules`) that actually specifies the content defining YANG modules including revision, supported features, deviations and any relevant additional data (e.g., revision labels). See [Section 3.2](#).

### [3.1.2](#). Simplified-Inline Method

The instance data set contains a list of content defining YANG modules including the revision date for each. Usage of this method implies that the modules are used without any deviations and with all features supported.

### [3.1.3](#). URI Method

The `same-schema-as-file` leaf SHALL contain a URI that references another YANG instance data file. The current instance data file will use the same content schema as the referenced file.

The referenced instance data file MAY have no `content-data` if it is used solely for specifying the `content-schema`.

If a referenced instance data file is not available, `content-schema` is unknown.

The URI method is advantageous when the user wants to avoid the overhead of specifying the `content-schema` in each instance data file: E.g., In Use Case 6, when the system creates a diagnostic file every minute to document the state of the server.

## [3.2](#). Examples

The following example is based on "UC1, Documenting Server Capabilities". It provides (a shortened) list of supported YANG modules and NETCONF capabilities for a server. It uses the `inline` method to specify the `content-schema`.

```
<?xml version="1.0" encoding="UTF-8"?>
<instance-data-set xmlns=
  "urn:ietf:params:xml:ns:yang:ietf-yang-instance-data">
  <name>acme-router-modules</name>
  <yid-version>1</yid-version>
```

---

```
<content-schema>
  <inline-module>
    ietf-yang-library@2016-06-21
  </inline-module>
  <inline-schema>

    </capability>
  </capabilities>
</netconf-state>
</content-data>
</instance-data-set>
```

Figure 1: XML Instance Data Set - Use case 1, Documenting server capabilities

The following example is based on "UC2, Preloading Default Configuration". It provides a (shortened) default rule set for a read-only operator role. It uses the inline method for specifying the content-schema.

```
<?xml version="1.0" encoding="UTF-8"?>
<instance-data-set xmlns=
  "urn:ietf:params:xml:ns:yang:ietf-yang-instance-data">
  <name>read-only-acm-rules</name>
  <yid-version>1</yid-version>
  <content-schema>
    <inline-module>ietf-yang-library@2019-01-04</inline-module>
    <inline-schema>
      <yang-library
        xmlns="urn:ietf:params:xml:ns:yang:ietf-yang-library">
        <module-set>
          <name>all</name>
          <module>
            <name>ietf-netconf-acm</name>
            <revision>2012-02-22</revision>
          </module>
        </module-set>
      </yang-library>
    </inline-schema>
  </content-schema>
  <revision>
    <date>1776-07-04</date>
    <description>Initial version</description>
  </revision>
  <description>Access control rules for a read-only role.</description>
  <content-data>
    <nacm xmlns="urn:ietf:params:xml:ns:yang:ietf-netconf-acm">
      <enable-nacm>true</enable-nacm>
      <read-default>deny</read-default>
      <exec-default>deny</exec-default>
      <rule-list>
        <name>read-only-role</name>
```

```

    <group>read-only-group</group>
    <rule>
      <name>read-all</name>
      <module-name>*</module-name>
      <access-operation>read</access-operation>
      <action>permit</action>
    </rule>
  </rule-list>
</nacm>
</content-data>
</instance-data-set>

```

Figure 2: XML Instance Data Set – Use case 2, Preloading access control data

The following example is based on UC5 Storing diagnostics data. An instance data set is produced by the server every 15 minutes that contains statistics about NETCONF. As a new set is produced periodically many times a day a revision-date would be useless; instead a timestamp is included.

```

{
  "ietf-yang-instance-data:instance-data-set": {
    "name": "acme-router-netconf-diagnostics",
    "yid-version": "1",
    "content-schema": {
      "same-schema-as-file": "file:///acme-diagnostics-schema.json",
    },
    "timestamp": "2018-01-25T17:00:38Z",
    "description":
      "NETCONF statistics",
    "content-data": {
      "ietf-netconf-monitoring:netconf-state": {
        "statistics": {
          "netconf-start-time ": "2018-12-05T17:45:00Z",
          "in-bad-hellos ": "32",
          "in-sessions ": "397",
          "dropped-sessions ": "87",
          "in-rpcs ": "8711",
          "in-bad-rpcs ": "408",

```

```
        "out-rpc-errors ": "408",
        "out-notifications": "39007"
    }
}
}
}
```

Figure 3: JSON Instance Data File example - UC5 Storing diagnostics data

#### 4. Backwards Compatibility

The concept of backwards compatibility and what changes are backwards compatible are not defined for instance data sets as it is highly dependent on the specific use case and the content-schema.

For instance data that is the result of a design or specification activity, some changes that may be good to avoid are listed. YANG uses the concept of managed entities identified by key values; if the connection between the represented entity and the key value is not preserved during an update, this may lead to problems.

- o If the key value of a list entry that represents the same managed entity as before is changed, the user may mistakenly identify the list entry as new.
- o If the meaning of a list entry is changed, but the key values are not (e.g., redefining an alarm-type but not changing its alarm-type-id) the change may not be noticed.
- o If the key value of a previously removed list entry is reused for a different entity, the change may be misinterpreted as reintroducing the previous entity.

#### 5. YANG Instance Data Model

##### 5.1. Tree Diagram

The following tree diagram [[RFC8340](#)] provides an overview of the data model.

```

module: ietf-yang-instance-data
  structure instance-data-set:
    +--rw name?                               string
    +--rw yid-version                          uint8
    +--rw content-schema
      | +--rw (content-schema-spec)?
      |   +--:(simplified-inline)
      |     | +--rw module*                   string
      |     +--:(inline) {inline-content-schema}?
      |       | +--rw inline-module*         string
      |       | +--rw inline-schema         <anydata>
      |       +--:(uri)
      |         +--rw same-schema-as-file?   inet:uri
    +--rw description?                        string
    +--rw contact?                           string
    +--rw organization?                       string
    +--rw datastore?                          ds:datastore-ref
    +--rw revision* [date]
      | +--rw date                            string
      | +--rw description?                   string
    +--rw timestamp?                          yang:date-and-time
    +--rw content-data?                       <anydata>

```

<CODE ENDS>
```

## [6.](#) Security Considerations

The YANG module defined in this document is designed as a wrapper specifying a format and a metadata header for YANG instance data defined by the content-schema. The data is designed to be accessed as a stored file or over any file access method or protocol.

The document does not specify any method to influence the behavior of a server.

Instance data files may contain sensitive data.

The header part is not security sensitive.

The security sensitivity of the instance data in the content part is completely dependent on the content schema. Depending on the nature of the instance data, instance data files MAY need to be handled in a secure way. The same kind of handling should be applied, that would be needed for the result of a read operation returning the same data.

Instance data files should be protected against modification or unauthorized access using normal file handling mechanisms. Care should be taken, when copying the original files or providing file access for additional users, not to reveal information unintentionally.

## [7.](#) IANA Considerations

This document registers one URI and one YANG module.

### [7.1.](#) URI Registration

This document registers one URI in the IETF XML registry [[RFC3688](#)]. Following the format in [RFC 3688](#), the following registration is requested to be made:

URI: urn:ietf:params:xml:ns:yang:ietf-yang-instance-data

Registrant Contact: The IESG.

XML: N/A, the requested URI is an XML namespace.

### [7.2.](#) YANG Module Name Registration

This document registers one YANG module in the YANG Module Names registry [[RFC6020](#)].

```
name: ietf-yang-instance-data
namespace: urn:ietf:params:xml:ns:yang:ietf-yang-instance-data
prefix: yid
reference: RFC XXXX
```

## [8.](#) Acknowledgments

For their valuable comments, discussions, and feedback, we wish to acknowledge Andy Bierman, Juergen Schoenwaelder, Rob Wilton, Joe Clarke, Kent Watsen Martin Bjorklund, Ladislav Lhotka, Qin Wu and other members of the Netmod WG.

#### [Appendix A](#). Open Issues

- o -

#### [Appendix B](#). Changes between revisions

v06 - v07

- o Updated terminology, use-cases
- o Many small changes based on WGLC

v05 - v06

- o Modified module name format, removed .yin or .yang extension
- o Removed pattern for module and inline-module. We want to allow the usage of revision-label later

v04 - v05

- o Updated according to YANG-Doctor review
- o Updated security considerations
- o Added a wrapping container for the schema, and renamed the data nodes in the inline and uri cases.
- o Allowed .yin for simplified-inline schema naming. Made date optional if it is not available in the YANG module.
- o Added a mandatory yid-version to the header metadata to allow later updates of the module.

v03 - v04

- o removed entity-tag and last-modified timestamp
- o Added simplified-inline method of content-schema specification

v02 - v03

- o target renamed to "content-schema" and "content defining YANG module(s)"
- o Made name of instance data set optional
- o Updated according to [draft-ietf-netmod-yang-data-ext-03](#)
- o Clarified that entity-tag and last-modified timestamp are encoded as metadata. While they contain useful data, the HTTP-header based encoding from Restconf is not suitable.

v01 - v02

- o Removed design time from terminology
- o Defined the format of the content-data part by referencing various RFCs and drafts instead of the result of the get-data and get operations.
- o Changed target-ptr to a choice
- o Inline target-ptr may include augmenting modules and alternatives to ietf-yang-library
- o Moved list of target modules into a separate <target-modules> element.
- o Added backwards compatibility considerations

v00 - v01

- o Added the target-ptr metadata with 3 methods
- o Added timestamp metadata
- o Removed usage of dedicated .yid file extension
- o Added list of use cases
- o Added list of principles
- o Updated examples

Internet-Draft

YANG Instance Data

February 2020

- o Moved detailed use case descriptions to appendix

## [Appendix C](#). Detailed Use Cases - Non-Normative

### [C.1](#). Use Cases

We present a number of use cases where YANG instance data is needed.

#### [C.1.1](#). Use Case 1: Early Documentation of Server Capabilities

A server has a number of server-capabilities that are defined in YANG modules and can be retrieved from the server using protocols like NETCONF or RESTCONF. Server capabilities include:

- o data defined in ietf-yang-library: YANG modules, submodules, features, deviations, schema-mounts, and datastores supported ([\[RFC8525\]](#))
- o alarms supported ([\[RFC8632\]](#))
- o data nodes and subtrees that support or do not support on-change notifications ([\[RFC8641\]](#))
- o netconf-capabilities in ietf-netconf-monitoring

While it is good practice to allow a client to query these capabilities from the live server, that is often not possible.

Often when a network node is released, an associated NMS (network management system) is also released with it. The NMS depends on the capabilities of the server. During NMS implementation, information about server capabilities is needed. If the information is not available early in some offline document, but only as instance data from the live network node, the NMS implementation will be delayed, because it has to wait until the network node is ready. Also assuming that all NMS implementors will have a correctly configured network nodes from which data can be retrieved, is a very expensive proposition. (An NMS may handle dozens of node types.)

Network operators often build their own home-grown NMS systems that need to be integrated with a vendor's network node. The operator needs to know the network node's server capabilities in order to do

this. Moreover, the network operator's decision to buy a vendor's product may even be influenced by the network node's OAM feature set documented as the server's capabilities.

Beside NMS implementors, system integrators and many others also need the same information early. Examples could be model driven testing, generating documentation, etc.

Most server-capabilities are relatively stable and change only during upgrade or due to licensing or the addition or removal of hardware. They are usually defined by a vendor at design time, before the product is released. It is feasible and advantageous to define/document them early e.g., in a YANG instance data File.

It is anticipated that a separate IETF document will define in detail how and which set of server capabilities should be documented.

#### [C.1.2.](#) Use Case 2: Preloading Data

There are parts of the configuration that must be fully configurable by the operator. However, often a simple default configuration will be sufficient.

One example is access control groups/roles and related rules. While a sophisticated operator may define dozens of different groups, often a basic (read-only operator, read-write system administrator, security-administrator) triplet will be enough. Vendors will often provide such default configuration data to make device configuration easier for an operator.

Defining access control data is a complex task. To help, the device vendor predefines a set of default groups (/nacm:nacm/groups) and rules for these groups to access specific parts of common models (/nacm:nacm/rule-list/rule).

YANG instance data files are used to document and/or preload the default configuration.

#### [C.1.3.](#) Use Case 3: Documenting Factory Default Settings

Nearly every server has a factory default configuration. If the system is really badly misconfigured or if the current configuration is to be abandoned, the system can be reset the default factory configuration.

In NETCONF, the <delete-config> operation can already be used to reset the startup datastore. There are ongoing efforts to introduce a new, more generic factory-reset operation for the same purpose [[I-D.ietf-netmod-factory-default](#)]

The operator currently has no way to know what the default configuration actually contains. YANG instance data can also be used to document the factory default configuration.
