      Registry Specification for Mandatory Access Control (MAC) Security Label
                               Formats
                    draft-ietf-nfsv4-lfs-registry-00.txt

Abstract

   In the past Mandatory Access Control (MAC) systems have used very
   rigid policies which were hardcoded into the particular protocol and
   platform. As MAC systems are more widely deployed additional
   flexibility in mechanism and policy is required. Where traditional
   trusted systems implemented Multi-Level Security (MLS) and integrity
   models, modern systems have expanded to include technologies such as
   type enforcement. Due to the wide range of policies and mechanisms
   it has proven through past efforts to be virtually impossible to
   accomodate all parties in one security label format and model.

   To allow multiple MAC mechanisms and label formats in a network, this
   document proposes a registry of label format specifications. This
   registry contains several identifiers to accomodate both integer and
   string preferences and associates those identifiers with an extensive
   document outlining the exact syntax and use of the particular label
   format.

1. Introduction

   With the acceptance of security labels in several mainstream
   operating systems the need to communicate labels between these
   systems becomes more important. In a typical client and server
   scenario, the client request to the server acts as a subject trying
   to access an object on the server [RFC7204]. Unfortunately these
   systems are diverse enough that attempts at establishing one common
   label format have been unsucessful. The reason for this is that
   systems implement different Mandatory Access Control (MAC) models,
   which typically do not share any common ground.

One solution is to define a single label format which consists of the union of the requirements of all MAC models/implementations. This is not ideal because it introduces an environment where many MAC models would either have blank fields for many of the label's components or will ignore the values that are present all together. This environment introduces waste and complexity where it is not needed. Additionally if a policy authority or identifier field is specified in the label format it would require a robust description that could be implemented which would lock policy administration into the described model.

Ideally a mechanism to address this problem should allow the most flexibility possible in terms of policy administration while providing a specification that is suffient to allow for implementation of the label format and understanding of the semantics of the label. This means that the label format specification would ideally contain a syntactic description of the label format and a description of the semantics for each component in the label. This allows protocols to specify the type of label and label semantics that it requires while leaving policy and policy administration to the individual organizations using the protocol in their environment.

Policy administration within an organization is a difficult problem. This should not be made even more difficult by having to request permission from external entities when crafting new policy or just making department specific modifications to existing policies. The policy authority field would allow an label format specification to specify a scheme for policy administration without forcing it on all users of security labels. However by agreeing to implement a particular label format specification, the protocol agrees to that policy administration mechanism when processing labels of that type.

2. Definitions

Label Format Specification: an identifier used by the client to establish the syntactic format of the security label and the semantic meaning of its components.

Multi-Level Security (MLS): a traditional model where objects are given a sensitivity level (Unclassified, Secret, Top Secret, etc.) and a category set [RH_MLS].

Object: a passive resource within the system that we wish to protect. Objects can be entities such as files, directories, pipes, sockets, and many other system resources relevant to the protection of the system state.

Subject: an active entity, usually a process, that is requesting
   access to an object.

3. Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT",
"SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this
document are to be interpreted as described in [RFC2119].

4. Exisiting Label Format Specifications

4.1. Commercial IP Security Option (CIPSO)

The Commercial IP Security Option (CIPSO) label format specification
is documented in [CIPSO]. While this draft has expired a long time
ago, it is the defacto standard for labeled networking. It is also
documented in [FIPS-188].

4.2. Common Architecture Label IPv6 Security Option (CALIPSO)

The Common Architecture Label IPv6 Security Option (CALIPSO) [CIPSO]
is a successor to CIPSO.

4.3. Flux Advanced Security Kernel (FLASK)

The Flux Advanced Security Kernel (FLASK) is an impelementation of an
architecture to provide flexible support for security policies.

5. Security Considerations

This document defines a mechanism to associate LFS identifier with a
document outlining the syntax and format of a label. There is no
security consideration in such an association. The label
specification documents referenced by each registration entry should
state security considerations for the label mechanism it specifies.

6. IANA Considerations

This section provides guidance to the Internet Assigned Numbers
Authority (IANA) regarding creation of a new registry in accordance
with [RFC5226].

This submission requests the creation of a new registry called
"Security Label Format Selection Registry". The new registry has the
following fields:

Label Format Selector: An integer number that maps to a particular
   label format, e.g., the CALIPSO label format defined by [RFC5570].
   The name space of this identifier has the range of 0..65,535.

Label Description: A human readable ASCII text string that describes
   the label format, e.g., "Common Architecture Label IPv6 Security
   Option (CALIPSO)". The length of this field is limited to 128
   bytes.

Status: A short ASCII text string indicating the status of an entry
   in the registry. The status field for most entries should have
   the value "active". In the case that a label format selection
   entry is obsolete, the status field of the obsoleted entry should
   be "obsoleted by entry NNN".

Label Format Specification: A reference to a stable, public document
   that specify the label format, e.g., an URL to [RFC5570].

6.1. Initial Registry

The initial assignments of the registry are as follows:

```
+-----------------+-----------------+--------+--------------------+
| Label Format    | Description     | Status | Reference          |
| Selector        |                 |        |                    |
+-----------------+-----------------+--------+--------------------+
| 0               | Reserved        | -      | -                  |
| 1 - 127         | Private Use     | -      | -                  |
| 128 - 255       | Experimental Use| -      | -                  |
| 256             | CIPSO (tag type | active | [[CIPSO] URL]      |
|                 | #1)             |        |                    |
| 257             | CALIPSO (RFC    | active | [[RFC5570] URL]    |
|                 | 5570)           |        |                    |
| 258             | FLASK Security  | active | [[FLASK] URL]      |
|                 | Context         |        |                    |
| 258 - 65535     | Unassigned      | -      | -                  |
+-----------------+-----------------+--------+--------------------+
```

                   Label Format Specifier Ranges

                              Table 1

6.2. Adding a New Entry to the Registry

A label format specification document is required to add a new entry
to this registry. If the label format document is inside the RFC
path, then The IANA Consideration section of the label format
document should clearly reference the Label Format Selection registry

and request allocation of a new entry. The well-known IANA policy,
Specification Required, as defined in section 4.1 of [RFC5226], will
be used to handle such requests. Note that "Specification Required"
policy implies this process requires a Designated Expert reviewer,
i.e., adding a new entry to this registry requires both a published
label format specification and a Designated Expert review.

6.3. Obsoleting a Label Format Selector

In the case that a label format selector number is assigned to a
label format and the label format specification is changed later, a
new selector assignment should be requested. The same Specification
Required IANA policy applies to such requests. The IANA
Consideration section of the updated label format specification
should be explicit in which old label selector assignment it
obsoletes. Below is an example of obsoleted entry in the registry:

```
+---------------+------------------+------------+-----------------+
| Label Format  | Description      | Status     | Reference       |
| Selector      |                  |            |                 |
+---------------+------------------+------------+-----------------+
| 0             | Reserved         | -          | -               |
| 1 - 127       | Private Use      | -          | -               |
| 128 - 255     | Experimental Use | -          | -               |
| 256           | CIPSO (tag type  | active     | [[CIPSO] URL]   |
|               | #1)              |            |                 |
| 257           | CALIPSO (RFC     | active     | [[RFC5570] URL] |
|               | 5570)            |            |                 |
| 258           | FLASK Security   | obsoleted  | [[FLASK] URL]   |
|               | Context          | by 263     |                 |
| ...           |                  |            |                 |
| 263           | FLASK Security   | active     | [new spec URL]  |
|               | Context (v2)     |            |                 |
| 264 - 65535   | Unassigned       | -          | -               |
+---------------+------------------+------------+-----------------+
```
