Registry Specification for Mandatory Access Control (MAC) Security Label Formats

draft-ietf-nfsv4-lfs-registry-06.txt

Abstract

In the past Mandatory Access Control (MAC) systems have used very rigid policies which were implemented in particular protocols and platforms. As MAC systems became more widely deployed, additional flexibility in mechanism and policy will be required. While traditional trusted systems implemented Multi-Level Security (MLS) and integrity models, modern systems have expanded to include technologies such as type enforcement. Due to the wide range of policies and mechanisms which need to be accommodated, it is unlikely that use of a single security label format and model will be viable.

To allow multiple MAC mechanisms and label formats to co-exist in a network, this document creates a registry of label format specifications. This registry contains label format identifiers and provides for the association of each such identifier with a corresponding extensive document document outlining the exact syntax and use of the particular label format.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at http://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on October 22, 2015.

1. Introduction

With the acceptance of security labels in several mainstream operating systems the need to communicate labels between these systems becomes more important. In a typical client and server scenario, the client request to the server acts as a subject trying to access an object on the server [RFC7204]. Unfortunately these systems are diverse enough that attempts at establishing one common label format have been unsucessful. The reason for this is that systems implement different Mandatory Access Control (MAC) models, which typically do not share any common ground.

Quigley, et al. Expires October 22, 2015 [Page 2]

One solution might be to define a single label format which consists of the union of the requirements of all MAC models/implementations, known at a given time. This approach is not desirable because it introduces an environment where many MAC models would either have blank fields for many of the label's components or where many implementations would ignore many of values that are present altogether. The resulting complexity would be likely to result in a confusing situation in which the interaction of fields that that derive from different MAC models is never clearly specified and the addition of new models or extension of existing models is unduly difficult.

An additional consideration is that if a policy authority or identifier field is specified in the label format it would require a robust description that encompassed multiple MAC models where implementation would lock policy administration into the described model.

Ideally a mechanism to address this problem should allow the most flexibility possible in terms of policy administration while providing a specification that is sufficient to allow for implementation of the label format and understanding of the semantics of the label. This means that the label format specification would ideally contain a syntactic description of the label format and a description of the semantics for each component in the label. This allows protocols to specify the type of label and label semantics that it requires while leaving policy and policy administration to the individual organizations using the protocol in their environment.

Policy administration within an organization is a difficult problem. This should not be made even more difficult by having to request permission from external entities when crafting new policy or just making department specific modifications to existing policies. The policy authority field would allow an label format specification to specify a scheme for policy administration without forcing it on all users of security labels. However by agreeing to implement a particular label format specification, the protocol agrees to that policy administration mechanism when processing labels of that type.

This document presents a registry of label format specifications to allow multiple MAC mechanisms and label formats to co-exist in a network. While the initial use of this registry is for the Network File System (NFS) protocol, it might also be referenced and used by other IETF protocols in future.

2. Definitions

- Label Format Specifier: an identifier used by the client to establish the syntactic format of the security label and the semantic meaning of its components.
- Label Format Specification: is a reference to a stable, public document that specifies the label format.
- Multi-Level Security (MLS): a traditional model where subjects are given a security level (Unclassified, Secret, Top Secret, etc.) and objects are given security labels that mandate the access of the subject to the object (see [BL73] and [RFC2401]).
- object: a passive resource within the system that we wish to protect. Objects can be entities such as files, directories, pipes, sockets, and many other system resources relevant to the protection of the system state.
- subject: an active entity, usually a process, user, or client, that is requesting access to an object.

3. Exisiting Label Format Specifications

3.1. IP Security Option (IPSO), Basic Security Option (BSO)

The "IP Security Option (IPSO)" label format is defined in [RFC1108]. IANA has assigned IPv4 Option 130 to the IPSO Basic Security Option (BSO). IPSO is the only IPv4 sensitivity label option implemented in commercial IP routers. IPSO BSO continues to have widespread implementation in hosts, and widespread deployment. For the purposes of this document, only the BSO labels in Table 1 on Page 3 of [RFC1108] are used.

In some locales, the BSO value "(Reserved 2)" is used for marking information that is considered "Restricted" by local policy, where "Restricted" is less sensitive than "Confidential" but more sensitive than "Unclassified".

3.2. Commercial IP Security Option (CIPSO)

The "Commercial IP Security Option (CIPSO)" label format is documented in [CIPSO] and in [FIPS-188]. While the cited Internet-Draft is long expired, it is widely supported in deployed MLS systems that support IPv4. IANA has assigned IPv4 option number 134 to CIPSO. CIPSO is defined ONLY as an IPv4 option. IANA has never assigned any IPv6 option value to CIPSO.

Quigley, et al. Expires October 22, 2015 [Page 4]

3.3. Common Architecture Label IPv6 Security Option (CALIPSO)

The "Common Architecture Label IPv6 Security Option (CALIPSO)" label format is specified in [RFC5570] and is defined for IPv6. As noted in Section 10 of [RFC5570] CALIPSO is a direct derivative of the IPv4 "Simple IP Security Option (SIPSO)", therefore CALIPSO is NOT derived from CIPSO in any way.

3.4. Flux Advanced Security Kernel (FLASK)

The Flux Advanced Security Kernel (FLASK) [FLASK99] is an impelementation of an architecture to provide flexible support for security policies. Section 2.1 of [FLASK99b], summarizes the architecture of FLASK to:

- describe the interactions between a subsystem which enforces security policy decisions and a subsystem which makes those decisions
- 2. the requirements on the components within each subsystem.

4. Security Considerations

This document defines a mechanism to associate the Label Format Specifier identifier with a document outlining the syntax and format of a label. There is no security consideration in such an association. The label specification documents referenced by each registration entry should state security considerations for the label mechanism it specifies.

5. IANA Considerations

This section provides guidance to the Internet Assigned Numbers Authority (IANA) regarding creation of a new registry in accordance with [RFC5226].

This submission requests the creation of a new registry called "Security Label Format Selection Registry". The new registry has the following fields:

Label Format Specifier: An integer number that maps to a particular label format, e.g., the CALIPSO label format defined by [RFC5570]. The name space of this identifier has the range of 0..65,535.

Label Description: A human readable ASCII ([RFC20]) text string that describes the label format, e.g., "Common Architecture Label IPv6 Security Option (CALIPSO)". The length of this field is limited to 128 bytes.

Status: A short ASCII text string indicating the status of an entry in the registry. The status field for most entries should have the value "active". In the case that a label format selection entry is obsolete, the status field of the obsoleted entry should be "obsoleted by entry NNN".

Label Format Specification: A reference to a stable, public document that specifies the label format, e.g., an URL to [RFC5570].

<u>5.1</u>. Initial Registry

The initial assignments of the registry are as follows:

Label Format Specifier	Description 	Status	Reference
0 1 - 127 128 - 255 256 257 258 259 260 - 65535	Reserved Private Use Experimental Use CIPSO (tag type #1) CALIPSO ([RFC5570]) FLASK Security Context IPSO Available for IANA Assignment	active active	[[<u>RFC5570</u>] URL]

Label Format Specifier Ranges

Table 1

5.2. Adding a New Entry to the Registry

A label format specification document is required to add a new entry to the "Security Label Format Selection Registry". If the label format document is inside the RFC path, then The IANA Consideration section of the label format document should clearly reference the Label Format Selection registry and request allocation of a new entry. The well-known IANA policy, Specification Required, as defined in section Required, will be used to handle such requests. Note that "Specification Required" policy implies this process requires a Designated Expert reviewer, i.e., adding a new entry to this registry requires both a published label format specification and a Designated Expert review.

In reviewing the published label format specification, the Designated Expert should consider whether or not the specification provides sufficient semantics for the object and subject labels to enforce the MAC model and policy administration when deployed within an organization. Another consideration is if the label format allows a correct and complete implementation of the protocol to process and enforce labels as a policy administration mechanism. Finally, to reduce interoperability issues, the review must determine if the new label format specification has clearly defined syntax and semantics for the proposed new labels.

5.3. Obsoleting a Label Format Specifier

In the case that a label format selector number is assigned to a label format and the label format specification is changed later, a new selector assignment should be requested. The same Specification Required IANA policy applies to such requests. The IANA Consideration section of the updated label format specification should be explicit in which old label selector assignment it obsoletes. Below is an example of obsoleted entry in the registry:

+	+	+	++
Label Format	Description	Status	Reference
Specifier	ĺ	İ	i i
+	+	+	++
0	Reserved	-	-
1 - 127	Private Use	-	-
128 - 255	Experimental Use	-	-
256	CIPSO (tag type	active	[[<u>FIPS-188</u>] URL]
	#1)		l I
257	CALIPSO	active	[[<u>RFC5570</u>] URL]
	([<u>RFC5570</u>])		l l
258	FLASK Security	obsoleted	[[<u>FLASK99</u>] URL]
	Context	by 263	l l
1	1		l l
263	FLASK Security	active	[new spec URL]
1	Context (v2)		l l
264 - 65535	Available for IANA	-	-
	Assignment		ĺ
+	+	+	++

Example Label Format Specifier Updated Ranges

Table 2

Quigley, et al. Expires October 22, 2015 [Page 7]

5.4. Modifying an Existing Entry in the Registry

A request to modify either the Description or the published label format specification will also require the Specification Required IANA policy to be applied. The Designated Expert reviewer will need to determine if the published label format specification either obsoletes the Label Format Specifier or updates the label syntax and/or model. If the Label Format Specifier is obsoleted, then the reviewer will follow the process defined in Section 5.3. Otherwise for the update of either the label syntax and/or the model, the reviewer will approve the change.
