Internet Engineering Task Force Internet-Draft Intended status: Best Current Practice Expires: May 15, 2019

# **Network Time Protocol Best Current Practices** draft-ietf-ntp-bcp-08

#### Abstract

The Network Time Protocol (NTP), currently on its fourth version, has been widely used since its initial publication. This documentation is a collection of Best Practices for general operation of time servers on the Internet from across the NTP community.

#### Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of <u>BCP 78</u> and <u>BCP 79</u>.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <a href="https://datatracker.ietf.org/drafts/current/">https://datatracker.ietf.org/drafts/current/</a>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on May 15, 2019.

## 1. Introduction

NTP Version 4 (NTPv4) has been widely used since its publication as  $\frac{\text{RFC 5905}}{\text{RFC5905}}$ . This documentation is a collection of best practices from across the NTP community.

The recommendations in this document are intended to help operators distribute time on their networks more accurately and more securely. It is intended to apply generally to a broad range of networks. Some specific networks may have higher accuracy requirements that require additional techniques beyond what is documented here.

Among the best practices covered are recommendatons for general network security, time protocol specific security, and NTP server and client configuration. NTP operation in embedded devices is also covered.

This document also contains information for protocol implementors who want to develop their own RFC 5905 [RFC5905] compliant implementations.

## **<u>1.1</u>**. Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in <u>BCP 14 [RFC2119] [RFC8174]</u> when, and only when, they appear in all capitals, as shown here.

## 2. Keeping NTP up to date

Many network security mechanisms rely on time as part of their operation. If attackers can spoof the time, they may be able to bypass or neutralize other security elements. For example, incorrect time can disrupt the ability to reconcile logfile entries on the affected system with events on other systems. Important ways to detect and protect computers and networks against undefined behavior and security threats related to time are to keep their NTP implementations current, use an appropriate number of trustworthy time sources, and properly monitor their time infrastructure.

There are always new ideas about security on the Internet, and an application which is secure today could be insecure tomorrow once an unknown bug (or a known behavior) is exploited in the right way.

[Page 3]

Even our definition of what is secure has evolved over the years, so code which was considered secure when it was written may turn out to be insecure after some time. By keeping NTP implementations current, having "enough" trustworthy time sources (Section 4.1), and properly monitoring their time infrastructure (Section 4.4), network operators can make sure that their time infrastructure is operating correctly and within specification, and is not being attacked or misused.

There are multiple versions of the NTP protocol in use, and multiple implementations in use, on many different platforms. The practices in this document are meant to apply generally to any implementation of <u>RFC 5905</u> [<u>RFC5905</u>]. It is recommended that that NTP users select an implementation that is actively maintained. Users should keep up to date on any known attacks on their selected implementation, and deploy updates containing security fixes as soon as practical.

### 3. General Network Security Best Practices

## <u>3.1</u>. <u>BCP 38</u>

Many network attacks rely on modifying the IP source address of a packet to point to a different IP address than the computer which originated it. UDP-based protocols such as NTP are generally more susceptible to spoofing attacks then other connection-oriented protocols. NTP control messages can generate a lot of data in response to a small query, which makes it more attractive as a vector for distributed denial-of-service attacks. (NTP Control messages are discussed further in <u>Section 4.3</u>). One documented instance of such an attack can be found here [1], and in [IMC14] and [NDSS14]. Mitigating source address spoofing attacks should be a priority of anyone administering NTP.

<u>BCP 38</u> [RFC2827] was approved in 2000 to address this. <u>BCP 38</u> [RFC2827] calls for filtering outgoing and incoming traffic to make sure that the source and destination IP addresses are consistent with the expected flow of traffic on each network interface. It is recommended that large corporate networks (and ISP's of any size) implement ingress and egress filtering. More information is available at the <u>BCP38</u> Info Web page [2].

### **<u>4</u>**. NTP Configuration Best Practices

This section provides general Best Practices. Best Practices that are implementation specific are compiled in the Appendices.

[Page 4]

Internet-Draft

## 4.1. Use enough time sources

An NTP implementation that is compliant with <u>RFC 5905</u> [<u>RFC5905</u>] takes the available sources of time and submits this timing data to sophisticated intersection, clustering, and combining algorithms to get the best estimate of the correct time. The description of these algorithms is beyond the scope of this document. Interested readers should read <u>RFC 5905</u> [<u>RFC5905</u>] or the detailed description of NTP in MILLS 2006 [<u>MILLS2006</u>]. These available sources must be truly redundant and derive their time from independent sources.

- o If there is only 1 source of time, the answer is obvious. It may not be a good source of time, but it's the only source of time that can be considered. Any issue with the time at the source will be passed on to the client.
- o If there are 2 sources of time and they agree well enough, then the best "time" can be calculated easily. But if one source fails, then the solution degrades to the single-source solution outlined above. And if the two sources don't agree, then it's impossible to know which one is correct by simply looking at the time.
- o If there are 3 sources of time, there is more data available to converge on a "best" time, and this time is more likely to be accurate. And the loss of one of the sources (by becoming unreachable or unusable) can be tolerated. But at that point, the solution degrades to the 2 source solution.
- o 4 or more sources of time is better, as long as the sources are diverse (<u>Section 4.2</u>). If one of these sources develops a problem there are still at least 3 other time sources.

Operators who are concerned with maintaining accurate time SHOULD use at least 4 independent, diverse sources of time. Four sources will provide sufficient backup in case one source goes down. If four sources are not available, operators MAY use fewer sources, subject to the risks outlined above.

But even with 4 or more sources of time, systemic problems can happen. For several hours before and after the June 2015 leap second, several operators implemented leap smearing while others did not, and many NTP end nodes could not determine an accurate time source because 2 of their 4 sources of time gave them consistent UTC/ POSIX time, while the other 2 gave them consistent leap-smeared time. See <u>Section 4.6.1</u> for more information.

[Page 5]

Monitor your NTP instances. If your time sources do not generally agree, find out why and either correct the problems or stop using defective servers. See <u>Section 4.4</u> for more information.

#### 4.2. Use a diversity of Reference Clocks

When using servers with attached hardware reference clocks, it is recommended that several different types of reference clocks be used. Having a diversity of sources with independent implementations means that any one issue is less likely to cause a service interruption.

Are all clocks on a network from the same vendor? They may have the same bugs. Even devices from different vendors may not be truly independent if they share common elements. Are they using the same base chipset? Are they all running the same version of firmware? Chipset and firmware bugs can happen, but they can be more difficult to diagnose than application software bugs. When having the correct time is of critical importance, it's ultimately up to operators to ensure that their sources are sufficiently independent, even if they are not under the operator's control.

A systemic problem with time from any satellite navigation service is possible and has happened. Sunspot activity can render satellite or radio-based time source unusable. If the time on your network must be correct close to 100% of the time, then even if you are using a satellite-based system, you must plan for those rare instances when the system is unavailable (or wrong!).

## 4.3. Control Messages

Some implementations of NTPv4 provide the NTP Control Messages which originally have been specified in <u>Appendix B of [RFC1305]</u> which defined NTPv3, but never have been part of the NTPv4 specification. (Work is being done to formally document the structure of these control messages in <u>draft-ietf-ntp-mode-6-cmds</u> [CTRLMSG] .)

The NTP Control Messages are designed to permit monitoring and optionally authenticated control of NTP and its configuration. Used properly, these facilities provide vital debugging and performance information and control. Used improperly, these facilities can be an abuse vector. For this reason, it is recommended that publiclyfacing NTP servers should block mode 6 queries from outside their organization.

The ability to use Mode 6 beyond its basic monitoring capabilities can be limited to authenticated sessions that provide a 'controlkey'. It can also be limited through mechanisms outside of the NTP

[Page 6]

Network Time Protocol BCP

specification, such as Access Control Lists, that only allow access from approved IP addresses.

The NTP Control Messages responses are much larger than the corresponding queries. Thus, they can be abused in high-bandwidth DDoS attacks. To provide protection for such abuse NTP server operators should deploy ingress filtering <u>BCP 38</u> [<u>RFC2827</u>].

# <u>4.4</u>. Monitoring

Use your NTP implementation's remote monitoring capabilities to quickly identify servers which are out of sync, and ensure correctness of the service. Monitor system logs for messages so problems and abuse attempts can be quickly identified.

If a system starts getting unexpected time replies from its time servers, that can be an indication that the IP address of the system is being forged in requests to its time server, and these abusers are trying to convince that time server to stop serving time to that system.

If a system is a broadcast client and its system log shows that it is receiving "early" time messages from its server, that is an indication that somebody may be forging packets from a broadcast server.

If a server's system log shows messages that indicates it is receiving timestamps that are earlier than the current system time, then either the system clock is unusually fast or somebody is trying to launch a replay attack against that server.

### 4.5. Using Pool Servers

It only takes a small amount of bandwidth and system resources to synchronize one NTP client, but NTP servers that can service tens of thousands of clients take more resources to run. Users who want to synchronize their computers should only synchronize to servers that they have permission to use.

The NTP pool project is a group of volunteers who have donated their computing and bandwidth resources to freely distribute time from primary time sources to others on the Internet. The time is generally of good quality, but comes with no guarantee whatsoever. If you are interested in using the pool, please review their instructions at <a href="http://www.pool.ntp.org/en/use.html">http://www.pool.ntp.org/en/use.html</a> [3].

[Page 7]

If you are a vendor who wishes to provide time service to your customers or clients, consider joining the pool and providing a "vendor zone" through the pool project.

If you want to synchronize many computers, consider running your own NTP servers that are synchronized by the pool, and synchronizing your clients to your in-house NTP servers. This reduces the load on the pool.

#### 4.6. Leap Second Handling

UTC is kept in agreement with the astronomical time UT1 [4] to within +/- 0.9 seconds by the insertion (or possibly a deletion) of a leap second. UTC is an atomic time scale whereas UT1 is based on the rotational rate of the earth. Leap seconds are not introduced at a fixed rate. They are announced by the International Earth Rotation and Reference Systems Service (IERS) in its Bulletin C [5] when necessary to keep UTC and UT1 aligned.

NTP time is based on the UTC timescale, and the protocol has the capability to broadcast leap second information. Some Global Navigation Satellite Systems (like GPS) or radio transmitters (like DCF77) broadcast leap second information, so if you are synced to an NTP server that is ultimately synced to a source that provides leap second notification you will get advance notification of impending leap seconds automatically.

Since the length of the UT1 day is generally slowly increasing [6], all leap seconds that have been introduced since the practice started in 1972 have been "positive" leap seconds, where a second is added to UTC. NTP also supports a "negative" leap second, where a second is removed from UTC, should that ever become necessary.

While earlier versions of NTP contained some ambiguity regarding when a leap second that is broadcast by a server should be applied by a client, <u>RFC 5905</u> is clear that leap seconds are only applied on the last day of a month. However, because some older clients may apply it at the end of the current day, it is recommended that NTP servers wait until the last day of the month before broadcasting leap seconds. Doing this will prevent older clients from applying a leap second at the wrong time. Note well that NTPv4's longest polling interval exceeds one day and thus a leap second announcement may be missed.

In circumstances where an NTP server is not receiving leap second information from an automated source, certain organizations maintain files which are updated every time a new leap second is announced:

[Page 8]

NIST: ftp://time.nist.gov/pub/leap-seconds.list

US Navy (maintains GPS Time): <u>ftp://tycho.usno.navy.mil/pub/ntp/leap-</u> seconds.list

IERS (announces leap seconds): https://hpiers.obspm.fr/iers/bul/bulc/ntp/leap-seconds.list

### 4.6.1. Leap Smearing

Some NTP installations may instead make use of a technique called "Leap Smearing". With this method, instead of introducing an extra second (or eliminating a second), NTP time will be slewed in small increments over a comparably large window of time (called the smear interval) around the leap second event. The smear interval should be large enough to make the rate that the time is slewed small, so that clients will follow the smeared time without objecting. Periods ranging from 2 to 24 hours have been used successfully. During the adjustment window, all the NTP clients' times may be offset from UTC by as much as a full second, depending on the implementation. But at least all clients will generally agree on what time they think it is!

Operators should NOTE WELL that using a leap-smear can cause your reported time to be "legally indefensible" and/or be a breach of compliance regulations.

The purpose of Leap Smearing is to enable systems that don't deal with the leap second event properly to function consistently, at the expense of fidelity to UTC during the smear window. During a standard leap second event, that minute will have 61 (or possibly 59) seconds in it, and some applications (and even some OS's) are known to have problems with that.

Clients that are connected to leap smearing servers MUST NOT apply the "standard" NTP leap second handling. So these clients must never have a leap second file loaded, and the smearing servers must never advertise to clients that a leap second is pending.

Any use of leap smearing servers should be limited to within a single, well-controlled environment. Leap Smearing MUST NOT be used f or public-facing NTP servers, as they will disagree with nonsmearing servers (as well as UTC) during the leap smear interval, and there is no standardized way for a client to detect that a server is using leap smearing. However, be aware that some public-facing servers may be configured this way anyway in spite of this guidance.

System Administrators are advised to be aware of impending leap seconds and how the servers (inside and outside their organization)

[Page 9]

they are using deal with them. Individual clients must never be configured to use a mixture of smeared and non-smeared servers. If a client uses smeared servers, the servers it uses must all have the same leap smear configuration.

## 5. NTP Security Mechanisms

In the standard configuration NTP packets are exchanged unprotected between client and server. An adversary that is able to become a Man-In-The-Middle is therefore able to drop, replay or modify the content of the NTP packet, which leads to degradation of the time synchronization or the transmission of false time information. A profound threat analysis for time synchronization protocols is given in <u>RFC 7384</u> [<u>RFC7384</u>]. NTP provides two internal security mechanisms to protect authenticity and integrity of the NTP packets. Both measures protect the NTP packet by means of a Message Authentication Code (MAC). Neither of them encrypts the NTP's payload, because this payload information is not considered to be confidential.

### 5.1. Pre-Shared Key Approach

This approach applies a symmetric key for the calculation of the MAC, which protects authenticity and integrity of the exchanged packets for an association. NTP does not provide a mechanism for the exchange of the keys between the associated nodes. Therefore, for each association, keys have to be exchanged securely by external means, and they have to be protected from disclosure. It is recommended that each association be protected by its own unique key. It is recommended that participants agree to refresh keys periodically. However, NTP does not provide a mechanism to assist in doing so.

<u>RFC 5905</u> [<u>RFC5905</u>] specifies a hash which must be supported for calculation of the MAC, but other algorithms may be supported as well. The MD5 hash is now considered to be too weak. Implementations will soon be available based on AES-128-CMAC [<u>NTPMAC</u>], and users are encouraged to use that when it is available.

To use this approach the communication partners have to exchange the key, which consists of a keyid with a value between 1 and 65534, inclusive, and a label which indicates the chosen digest algorithm. Each communication partner adds this information to its own key file.

Some implementations store the key in clear text. Therefore it should only be readable by the NTP process. Different keys are added line by line to the key file.

An NTP client establishes a protected association by appending the key to the server statement in its configuration file. Note that the NTP process has to trust the applied key.

### 5.2. Autokey

Autokey was specified in 2010 to provide automated key management and authentication of NTP servers. However, security researchers have identified vulnerabilities in the Autokey protocol, which make the protocol "useless". [7]

Autokey SHOULD NOT BE USED.

## 5.3. Network Time Security

Work is in progress on an enhanced replacement for Autokey, which is called Network Time Security (NTS) [NTSFORNTP]. As of July 2018, this effort was at draft #12, and in the 'Working Group Last Call' process. Readers are encouraged to adopt its mechanisms.

## 6. NTP Security Best Practices

This section lists some general NTP security practices, but these issues may (or may not) have been mitigated in particular versions of particular implementations. Contact the maintainers of your implementation for more information.

#### <u>6.1</u>. Minimizing Information Leakage

The base NTP packet leaks important information (including reference ID and reference time) that may be used in attacks [NDSS16], [CVE-2015-8138], [CVE-2016-1548]. A remote attacker can learn this information by sending mode 3 queries to a target system and inspecting the fields in the mode 4 response packet. NTP control queries also leak important information (including reference ID, expected origin timestamp, etc.) that may be used in attacks [CVE-2015-8139]. A remote attacker can learn this information by sending control queries to a target system and inspecting the response.

As such, mechanisms outside of the NTP protocol, such as Access Control Lists, should be used to limit the exposure of this information to allowed IP addresses, and keep it from remote attackers not on the list.

Hosts should only respond to NTP control queries from authorized parties. One way to do this is to only allow control queries from authenticated sources via authorized IP addresses.

Network Time Protocol BCP

A host that is not supposed to act as an NTP server that provides timing information to other hosts may additionally log and drop incoming mode 3 timing queries from unexpected sources. Note well that the easiest way to monitor ntpd's status is to send it a mode 3 query. It is recommended that operators should filter mode 3 queries at the edge, or make sure mode 3 queries are allowed only from trusted systems or networks.

A "leaf-node host" is a host that is using NTP solely for the purpose of adjusting its own system time. Such a host is not expected to provide time to other hosts, and relies exclusively on NTP's basic mode to take time from a set of servers. (That is, the host sends mode 3 queries to its servers and receives mode 4 responses from these servers containing timing information.) To minimize information leakage, leaf-node hosts should drop all incoming NTP packets except mode 4 response packets that come from known sources. Note well that proper monitoring of an ntpd instance includes checking the time of that ntpd instance.

### <u>6.2</u>. Avoiding Daemon Restart Attacks

<u>RFC 5905</u> [<u>RFC5905</u>] says NTP clients should not accept time shifts greater than the panic threshold. Specifically, <u>RFC 5905</u> says "PANIC means the offset is greater than the panic threshold PANICT (1000 s) and SHOULD cause the program to exit with a diagnostic message to the system log."

However, this behavior can be exploited by attackers [<u>NDSS16</u>], when the following two conditions hold:

- The operating system automatically restarts the NTP daemon when it quits. (Modern \*NIX operating systems are replacing traditional init systems with process supervisors, such as systemd, which can be configured to automatically restart any daemons that quit. This behavior is the default in CoreOS and Arch Linux. It is likely to become the default behavior in other systems as they migrate legacy init scripts to process supervisors such as systemd.)
- The NTP client is configured to ignore the panic threshold on all restarts.

In such cases, if the attacker can send the target an offset that exceeds the panic threshold, the client will quit. Then, when the client restarts, it ignores the panic threshold and accepts the attacker's large offset.

Hosts running with the above two conditions should be aware that the panic threshold does not protect them from attacks. The recommended and natural solution is not to run hosts with these conditions. Specifically, only ignore the panic threshold in cold-start situations if sufficient oversight and checking is in place to make sure that this is appropriate.

As an alternative, the following steps could be taken to mitigate the risk of attack.

- o Monitor NTP system log to detect when the NTP daemon has quit due to a panic event, as this could be a sign of an attack.
- o Request manual intervention when a timestep larger than the panic threshold is detected.
- o Configure the ntp client to only ignore the panic threshold in a cold start situation.
- o Implementations should prevent the NTP daemon from taking time steps that set the clock to a time earlier than the compile date of the NTP daemon.
- o Add "minsane" and "minclock" parameters to the ntp.conf file so ntpd waits until "enough" trusted sources of time agree on the correct time.

## 6.3. Detection of Attacks Through Monitoring

Users should monitor their NTP instances to detect attacks. Many known attacks on NTP have particular signatures. Common attack signatures include:

- 1. "Bogus packets" A packet whose origin timestamp does not match the value that expected by the client.
- "Zero origin packet" A packet with an origin timestamp set to zero [<u>CVE-2015-8138</u>].
- 3. A packet with an invalid cryptographic MAC [CCR16].

The observation of many such packets could indicate that the client is under attack.

Also, Kiss-o'-Death (KoD) packets can be used in denial of service attacks. Thus, the observation of even just one KoD packet with a high poll value could be sign that the client is under attack. See <u>Section 6.4</u> for more information.

## <u>6.4</u>. Kiss-of-Death Packets

The "Kiss-o'-Death" (KoD) packet is a rate limiting mechanism where a server can tell a misbehaving client to "back off" its query rate. It is important for all NTP devices to respect these packets and back off when asked to do so by a server. It is even more important for an embedded device, which may not have exposed a control interface for NTP.

That said, a client must only accept a KoD packet if it has a valid origin timestamp. Once a RATE packet is accepted, the client should increase its poll interval value (thus decreasing its polling rate) up to a reasonable maximum. This maximum can vary by implementation but should not exceed a poll interval value of 13 (2 hours). The mechanism to determine how much to increase the poll interval value is undefined in <u>RFC 5905</u> [<u>RFC5905</u>]. If the client uses the poll interval value sent by the server in the KoD packet, it must not simply accept any value. Using large interval values may open a vector for a denial-of-service attack that causes the client to stop querying its server [<u>NDSS16</u>].

The KoD mechanism relies on clients behaving properly in order to be effective. Some clients ignore the KoD packet entirely, and other poorly-implemented clients might unintentionally increase their poll rate and simulate a denial of service attack. Server administrators should be prepared for this and take measures outside of the NTP protocol to drop packets from misbehaving clients when these clients are detected.

## 6.5. Broadcast Mode Should Only Be Used On Trusted Networks

Per <u>RFC 5905</u> [<u>RFC5905</u>], NTP's broadcast mode is authenticated using symmetric key cryptography. The broadcast server and all of its broadcast clients share a symmetric cryptographic key, and the broadcast server uses this key to append a message authentication code (MAC) to the broadcast packets it sends.

Importantly, all broadcast clients that listen to this server must know the cryptographic key. This mean that any client can use this key to send valid broadcast messages that look like they come from the broadcast server. Thus, a rogue broadcast client can use its knowledge of this key to attack the other broadcast clients.

For this reason, an NTP broadcast server and all its client must trust each other. Broadcast mode should only be run from within a trusted network.

## 6.6. Symmetric Mode Should Only Be Used With Trusted Peers

In symmetric mode, two peers Alice and Bob can both push and pull synchronization to and from each other using either ephemeral symmetric passive (mode 2) or persistent symmetric active (NTP mode 1) packets. The persistent association is preconfigured and initiated at the active peer but not preconfigured at the passive peer (Bob). Upon receipt of a mode 1 NTP packet from Alice, Bob mobilizes a new ephemeral association if he does not have one already. This is a security risk for Bob because an arbitrary attacker can attempt to change Bob's time by asking Bob to become its symmetric passive peer.

For this reason, a host (Bob) should only allow symmetric passive associations to be established with trusted peers. Specifically, Bob should require each of its symmetric passive association to be cryptographically authenticated. Each symmetric passive association should be authenticated under a different cryptographic key.

The use of a different cryptographic key per peer prevents a Sybil attack, where a single malicious peer uses the same cryptographic key to set up multiple symmetric associations a target, and thus bias the results of the target's Byzantine fault tolerant peer selection algorithms.

### 7. NTP in Embedded Devices

Readers of this BCP already understand how important accurate time is for network computing. And as computing becomes more ubiquitous, there will be many small "Internet of Things" devices that require accurate time. These devices may not have a persistent batterybacked clock, so using NTP to set the correct time on power-up may be critical for proper operation. These devices may not have a traditional user interface, but if they connect to the Internet they will be subject to the same security threats as traditional deployments.

### 7.1. Updating Embedded Devices

Vendors of embedded devices have a special responsibility to pay attention to the current state of NTP bugs and security issues, because their customers don't have the ability to update their NTP implementation on their own. Those devices may have a single firmware upgrade, provided by the manufacturer, that updates all capabilities at once. This means that the vendor assumes the responsibility of making sure their devices have the latest NTP updates applied.

This should also include the ability to update information regarding which NTP server to connect to on these devices.

There is a catalog of NTP server abuse incidents, some of which involve embedded devices, on the Wikipedia page for NTP Server Misuse and Abuse [8].

#### 7.2. Server configuration

Vendors of embedded devices that need time synchronization should also carefully consider where they get their time from. There are several public-facing NTP servers available, but they may not be prepared to service requests from thousands of new devices on the Internet.

Vendors are encouraged to invest resources into providing their own time servers for their devices to connect to.

Vendors should read <u>RFC 4085</u> [<u>RFC4085</u>], which advises against embedding globally-routable IP addresses in products, and offers several better alternatives.

### 7.2.1. Get a vendor subdomain for pool.ntp.org

The NTP Pool Project offers a program where vendors can obtain their own subdomain that is part of the NTP Pool. This offers vendors the ability to safely make use of the time distributed by the Pool for their devices. Vendors are encouraged to support the pool if they participate. For more information, visit <a href="http://www.pool.ntp.org/en/vendors.html">http://www.pool.ntp.org/en/vendors.html</a> [9] .

## 8. NTP over Anycast

Anycast is described in <u>BCP 126</u> [<u>RFC4786</u>]. (Also see <u>RFC 7094</u> [<u>RFC7094</u>]). With anycast, a single IP address is assigned to multiple interfaces, and routers direct packets to the closest active interface.

Anycast is often used for Internet services at known IP addresses, such as DNS. Anycast can also be used in large organizations to simplify configuration of a large number of NTP clients. Each client can be configured with the same NTP server IP address, and a pool of anycast servers can be deployed to service those requests. New servers can be added to or taken from the pool, and other than a temporary loss of service while a server is taken down, these additions can be transparent to the clients.

NOTE WELL: Using a single anycast address for NTP should be done with care. It means each client will likely use a single time server source. A key element of a robust NTP deployment is each client using multiple sources of time. With multiple time sources, a client will analyze the various time sources, selecting good ones, and disregarding poor ones. If a single Anycast address is used, this analysis will not happen.

If clients are connected to an NTP server via anycast, the client does not know which particular server they are connected to. As anycast servers may arbitrarily enter and leave the network, the server a particular client is connected to may change. This may cause a small shift in time from the perspective of the client when the server it is connected to changes. It is recommended that anycast only be deployed in environments where these small shifts can be tolerated.

Configuration of an anycast interface is independent of NTP. Clients will always connect to the closest server, even if that server is having NTP issues. It is recommended that anycast NTP implementations have an independent method of monitoring the performance of NTP on a server. If the server is not performing to specification, it should remove itself from the Anycast network. It is also recommended that each Anycast NTP server have at least one Unicast interface, so its performance can be checked independently of the anycast routing scheme.

One useful application in large networks is to use a hybrid unicast/ anycast approach. Stratum 1 NTP servers can be deployed with unicast interfaces at several sites. Each site may have several Stratum 2 servers with two ethernet interfaces, or a single interface which can support multiple addresses. One interface has a unique unicast IP address. The second has an anycast IP interface (with a shared IP address per location). The unicast interfaces can be used to obtain time from the Stratum 1 servers globally (and perhaps peer with the other Stratum 2 servers at their site). Clients at each site can be configured to use the shared anycast address for their site, simplifying their configuration. Keeping the anycast routing restricted on a per-site basis will minimize the disruption at the client if its closest anycast server changes. Each Stratum 2 server can be uniquely identified on their unicast interface, to make monitoring easier.

#### **10**. IANA Considerations

This memo includes no request to IANA.

#### **<u>11</u>**. Security Considerations

Time is a fundamental component of security on the internet. The absence of a reliable source of current time subverts many common web authentication schemes, e.g., by allowing the use of expired credentials or by allowing for replay of messages only intended to be processed once.

Much of this document directly addresses how to secure NTP servers. In particular, see <u>Section 3</u>, <u>Section 5</u>, and <u>Section 6</u>.

There are several general threats to time synchronization protocols which are discussed in <u>RFC 7384</u> [<u>RFC7384</u>].

[NTSFORNTP] is an Internet-Draft that specifies the Network Time Security (NTS) mechanism and applies it specifically to NTP. Readers are encouraged to check the status of the draft, and make use of the methods it describes.

### Appendix A. NTP Implementation by the Network Time Foundation

The Network Time Foundation (NTF) provides the reference implementation of NTP, well-known under the name "ntpd". It is actively maintained and developed by NTF's NTP Project, with help from volunteers and NTF's supporters. This NTP software can be downloaded from ntp.org [10].

#### A.1. Use enough time sources

In addition to the recommendation given in Section Section 4.1 the ntpd implementation provides the 'pool' directive. Starting with ntp-4.2.6, this directive will spin up "enough" associations to provide robust time service, and will disconnect poor servers and add in new servers as-needed. If you have good reason, you may use the 'minclock' and 'maxclock' options of the 'tos' command to override the default values of how many servers are discovered through the 'pool' directive.

## A.2. NTP Control and Facility Messages

In addition to NTP Control Messages the ntpd implementation also offers the Mode 7 commands for monitoring and configuration.

If Mode 7 has been explicitly enabled to be used for more than basic monitoring it should be limited to authenticated sessions that provide a 'requestkey'.

As mentioned above, there are two general ways to use Mode 6 and Mode 7 requests. One way is to query ntpd for information, and this mode can be disabled with:

restrict ... noquery

The second way to use Mode 6 and Mode 7 requests is to modify ntpd's behavior. Modification of ntpd's configuration requires an

authenticated session by default. If no authentication keys have been specified no modifications can be made. For additional protection, the ability to perform these modifications can be controlled with:

```
restrict ... nomodify
```

Users can prevent their NTP servers from considering query/ configuration traffic by default by adding the following to their ntp.conf file:

restrict default -4 nomodify notrap nopeer noquery

restrict default -6 nomodify notrap nopeer noquery

restrict source nomodify notrap noquery
# nopeer is OK if you don't use the 'pool' directive

### A.3. Monitoring

The reference implementation of NTP allows remote monitoring. Access to this service is generally controlled by the "noquery" directive in NTP's configuration file (ntp.conf) via a "restrict" statement. The syntax reads:

restrict address mask address\_mask noquery

If a system is using broadcast mode and is running ntp-4.2.8p6 or later, use the 4th field of the ntp.keys file to specify the IPs of machines that are allowed to serve time to the group.

### A.4. Leap Second File

The use of leap second files requires ntpd 4.2.6 or later. After fetching the leap seconds file onto the server, add this line to ntpd.conf to apply and use the file:

leapfile "/path/to your/leap-file"

You may need to restart ntpd to apply this change.

ntpd servers with a manually configured leap second file will ignore leap second information broadcast from upstream NTP servers until the leap second file expires. If no valid leap second file is available then a leap second notification from an attached reference clock is always accepted by ntpd.

If no valid leap second file is available, a leap second notification may be accepted from upstream NTP servers. As of ntp-4.2.6, a majority of servers must provide the notification before it is accepted. Before 4.2.6, a leap second notification would be accepted if a single upstream server of a group of configured servers provided a leap second notification. This would lead to misbehavior if single NTP servers sent an invalid leap second warning, e.g. due to a faulty GPS receiver in one server, but this behavior was once chosen because in the "early days" there was a greater chance that leap second information would be available from a very limited number of sources.

### <u>A.5</u>. Leap Smearing

Leap Smearing was introduced in ntpd versions 4.2.8.p3 and 4.3.47, in response to CLIENT requests. Support for leap smearing is not configured by default and must be added at compile time. In addition, no leap smearing will occur unless a leap smear interval is specified in ntpd.conf . For more information, refer to <a href="http://bk.ntp.org/ntp-stable/README.leapsmear?PAGE=anno">http://bk.ntp.org/ntp-stable/README.leapsmear?PAGE=anno</a> [11].

## A.6. Configuring ntpd

See <u>https://support.ntp.org/bin/view/Support/ConfiguringNTP</u> [12] for additional information on configuring ntpd.

### A.7. Pre-Shared Keys

Each communication partner must add the keyid information to their key file in the form:

keyid label key

An ntpd client establishes a protected association by appending the option "key keyid" to the server statement in ntp.conf:

server address key keyid

A key is deemed trusted when its keyid is added to the list of trusted keys by the "trustedkey" statement in ntp.conf.

trustedkey keyid\_1 keyid\_2 ... keyid\_n

Starting with ntp-4.2.8p7 the ntp.keys file accepts an optional 4th column, a comma-separated list of IPs that are allowed to serve time. Use this feature. Note, however, that an adversarial client that knows the symmetric broadcast key could still easily spoof its source IP to an IP that is allowed to serve time. (This is easy to do because the origin timestamp on broadcast mode packets is not

validated by the client. By contrast, client/server and symmetric modes do require origin timestamp validation, making it more difficult to spoof packets [CCR16].
