### OAuth 2.0 Incremental Authorization
### draft-ietf-oauth-incremental-authz-00

Abstract

   OAuth 2.0 authorization requests that include every scope the client
   might ever need can result in over-scoped authorization and a sub-
   optimal end-user consent experience.  This specification enhances the
   OAuth 2.0 authorization protocol by adding incremental authorization,
   the ability to request specific authorization scopes as needed, when
   they're needed, removing the requirement to request every possible
   scope that might be needed upfront.

Status of This Memo

   This Internet-Draft is submitted in full conformance with the
   provisions of BCP 78 and BCP 79.

   Internet-Drafts are working documents of the Internet Engineering
   Task Force (IETF).  Note that other groups may also distribute
   working documents as Internet-Drafts.  The list of current Internet-
   Drafts is at https://datatracker.ietf.org/drafts/current/.

   Internet-Drafts are draft documents valid for a maximum of six months
   and may be updated, replaced, or obsoleted by other documents at any
   time.  It is inappropriate to use Internet-Drafts as reference
   material or to cite them other than as "work in progress."

   This Internet-Draft will expire on December 30, 2018.

## 1.  Introduction

OAuth 2.0 clients may offer multiple features that requiring user
authorization, but commonly not every user will use each feature.
Without incremental authentication, applications need to either
request all the possible scopes they need upfront, potentially
resulting in a bad user experience, or track each authorization grant
separately, complicating development.

The goal of incremental authorization is to allow clients to request
just the scopes they need, when they need them, while allowing them
to store a single authorization grant for the user that contains the
sum of the scopes granted.  Thus, each new authorization request
increments the scope of the authorization grant, without the client
needing to track a separate authorization grant for each group of
scopes.

## 2.  Notational Conventions

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in Key words for use in RFCs to Indicate Requirement Levels [RFC2119].  If these words are used without being spelled in uppercase then they are to be interpreted with their normal natural language meanings.

## 3.  Terminology

In addition to the terms defined in referenced specifications, this document uses the following terms:

"OAuth"  In this document, OAuth refers to OAuth 2.0 [RFC6749].

## 4.  Incremental Auth for Confidential Clients

For confidential clients, such as web servers that can keep secrets, the authorization endpoint SHOULD treat scopes that the user already granted differently on the consent user interface.  Typically such scopes are hidden for new authorization requests, or at least there is an indication that the user already approved them.

By itself, this property of the authorization endpoint enables incremental authorization.  The client can track every scope they've ever requested, and include those scopes on every new authorization request.

To avoid the need for confidential clients to re-request already authorized scopes, authorization servers MAY support an additional "include_granted_scopes" parameter in the authorization request. This parameter, enables the client to request tokens during the authorization grant exchange that represent the full scope of the user's grant to the application including any previous grants, without the app needing to track the scopes directly.

The client indicates they wish the new authorization grant to include previously granted scopes by sending the following additional parameter in the OAuth 2.0 Authorization Request (Section 4.1.1 of [RFC6749].) using the following additional parameter:

include_granted_scopes  OPTIONAL.  Either "true" or "false".  When
   "true", the authorization server SHOULD include previously granted
   scopes for this client in the new authorization grant.

## 5.  Incremental Auth for Public Clients

   Unlike with confidential clients, it is NOT RECOMMEND to
   automatically approve OAuth requests for public clients without user
   consent (see Section 10.2 of OAuth 2.0 [RFC6749], and Section 8.6 of
   OAuth 2.0 [RFC8252]), thus authorization grants shouldn't contain
   previously authorized scopes in the manner described above for
   confidential clients.

   Public clients (and confidential clients using this technique) should
   instead track the scopes for every authorization grant, and only
   request yet to be granted scopes during incremental authorization.
   In the past, this would result in multiple discrete authorization
   grants that would need to be tracked.  To enable incrementing a
   single authorization grant for public clients, the client supplies
   their existing refresh token during the authorization code exchange,
   and receives new authorization tokens with the scope of the previous
   and current authorization grants.

   The client sends the previous refresh token in the OAuth 2.0 Access
   Token Request (Section 4.1.3 of [RFC6749].) using the following
   additional parameter:

   existing_grant  OPTIONAL.  The refresh token from the existing
      authorization grant.

   When processing the token exchange, in addition to the normal
   processing of such a request, the token endpoint MUST verify that
   token provided in the "existing_grant" parameter is unexpired and
   unrevoked, and was issued to the same client id and relates to the
   same user as the current authorization grant.  If this verification
   succeeds, the new refresh token issued in the Access Token Response
   (Section 4.1.4 of ) SHOULD include authorization for the scopes in
   the previous grant.

## 6.  Usability Considerations

## 6.1.  Handling Denials

   A core principle of OAuth is that users may deny authorization
   requests for any reason.  This remains true for incremental
   authorization requests.  In the case of incremental authorization,
   clients may already have a valid authorization and receive a denial
   for an incremental authorization request (that is, an "access_denied"
   error code as defined in Section 4.1.2.1 of OAuth 2.0 [RFC6749]).
   Clients should SHOULD handle such errors gracefully and not discard
   any existing authorization grants if the user denies an incremental
   authorization request.  Clients SHOULD NOT immediately request the

same incremental authorization again, as this may result in an
infinite denial loop (and the end-user feeling badgered).

## 7.  Alternative Approaches

### 7.1.  Alternative for Public Clients

It is possible for OAuth clients to maintain multiple authorizations
per user for feature-specific scopes without needing the feature
documented in this specification.  For example, an app could maintain
an authorization for the contacts and one for calendar, and store
them separately.

This specification offers a convenience that a single authorization
grant can be managed that represents all the scope granted so far,
rather than needing to maintain multiple, however it does require
that all grants are made from a single end-user account (as
authorization servers cannot typically combine grants from multiple
users).  Apps where users may wish to authorize separate end-user
accounts for different features should consider using the alternative
documented above.

### 7.2.  Alternative for Confidential Clients

An alternative incremental auth design for confidential clients is to
ask for authorization scopes as they are needed and keep a running
record of all granted scopes.  In this way each incremental
authorization request would include all scopes granted so far, plus
the new scope needed.  Authorization servers can see the existing
scopes and only display the new scopes for approval (and likely to
inform the user of the existing grants).  This approach can be
performed using RFC 6749 without additions, but requires the client
to keep track of every authorization grant.

Confidential clients can also use the alternative documented for
public clients in Section 7.1.

## 8.  Privacy Considerations

### 8.1.  Requesting Authorization In Context

The goal of incremental authorization is to enhance end-user privacy
by allowing clients to request only the authorization scopes needed
in the context of a particular user action, rather than asking for
ever possible scope upfront.  For example, an app may offer calendar
and contacts integration, and an extension of OAuth like OpenID
Connect for sign-in.  Such an app should first sign the user in with
just the scopes needed for that.  If later the user interacts with

the calendar or contacts features then, and only then, should the
requires scopes be requested.  By using this specification, apps can
improve the privacy choices of end-users by only requesting the
scopes they need in context.

Clients authorizing the user with an authorization server that
supports incremental auth SHOULD ask for the minimal authorization
scope for the user's current context, and use this specification to
add authorization scope as required.

## 8.2.  Preventing Overbroad Authorization Requests

When this specification is implemented, clients should have no
technical reason to make overbroad authorization requests (i.e.
requesting every possible scope, even ones they don't immediately
need).  It is therefore RECOMMENDED for authorization servers to
limit the authorization scope that can be requested in a single
authorization to what would reasonably be needed by a single feature.

## 8.3.  Authorization Correlation

Incremental authorization is designed for use-cases where it's the
same user authorizing each request, and thus all incremental
authorization grants are correlated to that one user (by being merged
into a single authorization grant).  For applications where users may
wish to connect different user accounts for different features (e.g.
contacts from one account, and calendar from another) it is
RECOMMENDED to instead allow multiple unrelated authorizations, as
documented in Section 7.1.

The goal of this specification is to improve end-user privacy by
giving them more choice over which scopes they grant access to.
Previously many apps would request an overly large number of scopes
upfront (typically for all the features of the app, rather than the
subset that the user is currently wishing to use).  The scopes in
such authorization grants are necessarily correlated with the same
user as they are contained in a single authorization grant.
Implementing this specification doesn't change that attribute, but it
does improve user privacy overall by empowering the user to grant
access in a more granular way.

## 9.  Security Considerations

## 9.1.  Public Client Impersonation

As documented in Section 8.6 of RFC 8252 [RFC8252], some public
clients are susceptible to client impersonation, depending on the
type of redirect URI used.  If the "include_granted_scopes" feature

documented in Section 4 is used by an impersonating client, it may
receive a greater authorization grant than the user specifically
approved for that client.  For this reason, the
"include_granted_scopes" feature MUST NOT be enabled for such public
client requests.

Note that there is no such restriction on the use of "existing_grant"
feature documented in Section 5.  While it is designed for public
clients, it MAY be supported for all client types.

## 10.  IANA Considerations

This specification makes a registration request as follows:

### 10.1.  OAuth Parameters Registry

This specification registers the following parameters in the IANA
OAuth Parameters registry defined in OAuth 2.0 [RFC6749].

o  Parameter name: include_granted_scopes

o  Parameter usage location: authorization request

o  Change controller: IESG

o  Specification document(s): this document

o  Parameter name: existing_grant

o  Parameter usage location: token request

o  Change controller: IESG

o  Specification document(s): this document
