## YANG Modules for Service Assurance

### Abstract

This document specifies YANG modules for representing assurance graphs. These graphs represent the assurance of a given service by decomposing it into atomic assurance elements called subservices. A companion document, Service Assurance for Intent-based Networking Architecture, presents an architecture for implementing the assurance of such services.

The YANG data models in this document conforms to the Network Management Datastore Architecture (NMDA) defined in RFC 8342.

### Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <https://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on 7 July 2023.

## 1. Introduction

[[I-D.ietf-opsawg-service-assurance-architecture](#)] describes an architecture and a set of involved components for service assurance, called Service Assurance for Intent-Based Networking (SAIN). This document complements the architecture by specifying a data model for the interfaces between components. More specifically, the document provides YANG modules for the purpose of service assurance in a format that is:

- \*machine-readable

- \*vendor independent

- \*augmentable such that SAIN agents from Figure 1 of [[I-D.ietf-opsawg-service-assurance-architecture](#)] can support and expose new subservices to SAIN orchestrators and collectors.

### 1.1. Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [[RFC2119](#)] [[RFC8174](#)] when, and only when, they appear in all capitals, as shown here.

The terms used in this document are defined in [[I-D.ietf-opsawg-service-assurance-architecture](#)].

The meanings of the symbols in the tree diagrams are defined in [[RFC8340](#)].

## 2. YANG Modules Overview

The main YANG module, "ietf-service-assurance" ([Section 3](#)), defines objects for assuring network services based on their decomposition into so-called subservices. The subservices are hierarchically organized by dependencies. The subservices, along with the dependencies, constitute an assurance graph. This module should be supported by an agent, able to interact with the devices in order to produce a health status and symptoms for each subservice in an

assurance graph. This module is intended for the following use cases:

\*Assurance graph configuration:

- Subservices: configure a set of subservices to assure, by specifying their types and parameters.

- Dependencies: configure the dependencies between the subservices, along with their type.

\*Assurance telemetry: export the assurance graph with health status and symptoms for each node.

The module is also intended to be exported by the SAIN collector which aggregates the output of several SAIN agents to provide the global assurance graph. In that case, only the telemetry export use case is considered.

The modules presented in this document conform to the Network Management Datastore Architecture defined in [[RFC8342](#)].

The second YANG module, "ietf-service-assurance-device" ([Section 5](#)), augments the "ietf-service-assurance" module by adding support for the device subservice. Additional subservice types might be added following a similar approach.

The third YANG module, "ietf-service-assurance-interface" ([Section 6](#)), augments the "ietf-service-assurance" module as well, by adding support for the interface subservice.

We provide additional examples in the appendix. The module "example-service-assurance-device-acme" ([Appendix A](#)) augments the "ietf-service-assurance-device" module to customize it for devices of the fictional ACME Corporation. Additional vendor-specific parameters might be added following a similar approach. We also provide the modules "example-service-assurance-ip-connectivity" and "example-service-assurance-is-is" ([Appendix B](#)) to model the example in Figure 2 from Section 3.1 of [[I-D.ietf-opsawg-service-assurance-architecture](#)].

### **3. Base IETF Service Assurance YANG Module**

#### **3.1. Concepts**

The "ietf-service-assurance" YANG module assumes a set of subservices, to be assured independently. A subservice is a feature

or a subpart of the network system that a given service instance depends on. Examples of subservice types include:

\*device: whether a device is healthy, and if not, what are the symptoms. Such a subservice might monitor the device resources such as CPU, RAM or Ternary Content-Addressable Memory (TCAM). Potential symptoms are "CPU overloaded", "Out of RAM", or "Out of TCAM".

\*ip-connectivity: given two IP addresses bound to two devices, what is the quality of the IP connectivity between them. Potential symptoms are "No route available" or "Equal Cost Multiple Paths (ECMP) Imbalance".

An instance of the device subservice is representing a subpart of the network system, namely a specific device. An instance of the ip-connectivity subservice representing a feature of the network, namely the connectivity between two specific IP addresses on two devices. In both cases, these subservices might depend on other subservices, for instance, the connectivity might depend on a subservice representing the routing system and on a subservice representing ECMP.

The two example subservices presented above need different sets of parameters to fully characterize one of their instance. An instance of the device subservice is fully characterized by a single parameter allowing to identify the device to monitor. For ip-connectivity subservice, at least the device and IP address for both ends of the link are needed to fully characterize an instance.

The base model presented in this section specifies a single type of subservice, which represents service instances. Such nodes play a particular role in the assurance graph because they represent the starting point, or root, for the assurance graph of the corresponding service instance. The parameters required to fully identify a service instance are the name of the service and the name of the service instance. To support other types of subservice such as 'device' or 'ip-connectivity', the "ietf-service-assurance" module is intended to be augmented.

The dependencies are modelled as a list: each subservice contains a list of references to its dependencies. That list can be empty if the subservice instance does not have any dependencies.

By specifying service instances and their dependencies in terms of subservices, one defines a global assurance graph. That assurance graph is the result of merging all the individual assurance graphs for the assured service instances. Each subservice instance is expected to appear only one in the global assurance graph even if

several service instances depend on it. For example, an instance of the device subservice is a dependency of every service instance that rely on the corresponding device. The assurance graph of a specific service instance is the subgraph obtained by traversing the global assurance graph through the dependencies starting from the specific service instance.

An assurance agent configured with such a graph is expected to produce, for each configured subservice: a health-status indicating how healthy the subservice is and when the subservice is not healthy, a list of symptoms explaining why the subservice is not healthy.

### **3.2. Tree View**

The following tree diagram [[RFC8340](#)] provides an overview of the "ietf-service-assurance" module.

```

module: ietf-service-assurance
  +--ro assurance-graph-last-change      yang:date-and-time

```

The date of last change "assurance-graph-last-change" is read only. It must be updated each time the graph structure is changed by addition or deletion of subservices, dependencies or modification of

their configurable attributes, including their maintenance status. Such modifications correspond to a structural change in the graph. The date of last change is useful for a client to quickly check if there is a need to update the graph structure. A change in the health-score or symptoms associated to a service or subservice does not change the structure of the graph and thus has no effect on the date of last change.

The "subservice" list contains all the subservice instances currently known by the server (i.e. SAIN agent or SAIN collector). A subservice declaration MUST provide:

- \*A subservice type ("type"): reference to an identity that inherits from "subservice-base", which is the base identity for any subservice type.

- \*An id ("id"): string uniquely identifying the subservice among those with the same type,

The type and id uniquely identify a given subservice.

The "last-change" indicates when the dependencies or maintenance status of this particular subservice were last modified.

The "label" is a human-readable description of the subservice.

The presence of "under-maintenance" container inhibits the emission of symptoms for that subservice and subservices that depend on them. In that case, a "contact" MUST be provided to indicate who or which software is responsible for the maintenance. See Section 3.6 of [\[I-D.ietf-opsawg-service-assurance-architecture\]](#) for a more detailed discussion.

The "parameter" choice is intended to be augmented in order to describe parameters that are specific to the current subservice type. This base module defines only the subservice type representing service instances. Service instances MUST be modeled as a particular type of subservice with two parameters, "service" and "instance-name". The "service" parameter is the name of the service defined in the network orchestrator, for instance "point-to-point-l2vpn". The "instance-name" parameter is the name assigned to the particular instance to be assured, for instance the name of the customer using that instance.

The "health-score" contains a value normally between 0 and 100 indicating how healthy the subservice is. As mentioned in the health-score definition, the special value -1 can be used to specify that no value could be computed for that health-score, for instance if some metric needed for that computation could not be collected.

The "symptoms-history-start" is the cutoff date for reporting symptoms. Symptoms that were terminated before that date are not reported anymore in the model.

The status of each subservice contains a list of symptoms. Each symptom is specified by

- \*an identifier "symptom-id" which identifies the symptom locally to an agent,
- \*an agent identifier "agent-id" which identifies the agent raising the symptom,
- \*a "health-score-weight" specifying the impact to the health score incurred by this symptom,
- \*a "start-date-time" indicating when the symptom became active and
- \*a "stop-date-time" indicating when the symptom stopped being active, that field is not present if the symptom is still active.

In order for the pair "agent-id" and "symptom-id" to uniquely identify a symptom, the following is necessary:

- \*The "agent-id" MUST be unique among all agents of the system
- \*The "symptom-id" MUST be unique among all symptoms raised by the agent

Note that "agent-id" and "symptom-id" are leafrefs pointing to the objects defined later in the document. While the combination of "symptom-id" and "agent-id" is sufficient as a unique key list, the "start-date-time" second key helps to sort and retrieve relevant symptoms.

The "dependency" list contains the dependencies for the current subservice. Each of them is specified by a leafref to both "type" and "id" of the target dependencies. A dependency has a type indicated in the "dependency-type" field. Two types are specified in the model:

- \*Impacting: such a dependency indicates an impact on the health of the dependent,
- \*Informational: such a dependency might explain why the dependent has issues but does not impact its health.

To illustrate the difference between "impacting" and "informational", consider the interface subservice, representing a network interface. If the device to which the network interface

belongs goes down, the network interface will transition to a "down" state as well. Therefore, the dependency of the interface subservice towards the device subservice is "impacting". On the other hand, a dependency towards the ecmp-load subservice, which checks that the load between ECMP remains stable throughout time, is only "informational". Indeed, services might be perfectly healthy even if the load distribution between ECMP changed. However, such an instability might be a relevant symptom for diagnosing the root cause of a problem.

Within the container "agents", the list "agent" contains the list of symptoms per agent. The key of the list is the "id", which MUST be unique among agents of a given assurance system. For each agent, the list "symptoms-description" maps an "id" to its "description". The "id" MUST be unique among the symptoms raised by the agent.

Within the container "assured-services", the list "assured-service" contains the subservices indexed by assured service instances. For each service type, identified by the "service" leaf, all instances of that service are listed in the "instances" list. For each instance, identified by the "name" leaf, the "subservices" list contains all descendant subservices that are part of the assurance graph for that specific instance. These imbricated lists provide a query optimization to get the list of subservices in that assurance graph in a single query, instead of recursively querying the dependencies of each subservice, starting from the node representing the service instance.

The relation between the health score ("health-score") and the health-score-weight of the currently active symptoms is not explicitly defined in this document. The only requirement is that a health score that is strictly smaller than 100 (the maximal value) must be explained by at least one symptom. A way to enforce that requirement is to first detect symptoms and then compute the health score based on the health-score-weight of the detected symptoms. As an example, such a computation could be to sum the health-score-weight of the active symptoms, subtract that value from 100 and change the value to 0 if negative. The relation between health-score and health-score-weight is left to the implementor (of an agent [[I-D.ietf-opsawg-service-assurance-architecture](#)]).

Keeping the history of the graph structure is out of scope for this YANG module. Only the current version of the assurance graph can be fetched. In order to keep the history of the graph structure, some time-series database (TSDB) or similar storage must be used.

### 3.3. YANG Module

```
<CODE BEGINS> file "ietf-service-assurance@2022-08-10.yang"
```

```

module ietf-service-assurance {
  yang-version 1.1;
  namespace "urn:ietf:params:xml:ns:yang:ietf-service-assurance";
  prefix sain;

  import ietf-yang-types {
    prefix yang;
    reference
      "RFC 6991: Common YANG Data Types";
  }

<CODE ENDS>

### 3.4. Rejecting Circular Dependencies

The statuses of services and subservices depend on the statuses of their dependencies, and thus circular dependencies between them prevents the computation of statuses. The SAIN architecture document [[I-D.ietf-opsawg-service-assurance-architecture](#)] discusses in Section 3.1.1 how such dependencies appear and how they could be removed. The responsibility of avoiding such dependencies falls to the SAIN orchestrator. However, we specify in this section the expected behavior when a server supporting the `ietf-service-assurance` module receives a data instance containing circular dependencies.

Enforcing the absence of circular dependencies as a YANG constraint falls back to implementing a graph traversal algorithm with XPath and checking that the current node is not reachable from its dependencies. Even with such a constraint, there is no guarantee that merging two graphs without dependency loops will result in a graph without dependency loops. Indeed, the Section 3.1.1 of [[I-D.ietf-opsawg-service-assurance-architecture](#)] presents an example where merging two graphs without dependency loops results in a graph with a dependency loop.

Therefore, a server implementing the `ietf-service-assurance` module MUST check that there is no dependency loop whenever the graph is modified. A modification creating a dependency loop MUST be rejected.

## 4. Guidelines for Defining New Subservice Types

The base YANG module defined in [Section 3.3](#) only defines a single type of subservices that represent service instances. As explained above, this model is meant to be augmented so that a variety of subservices can be used in the assurance graph. In this section, we propose some guidelines for specifying such extensions at IETF.

The mechanism to add a new subservice type is to define a new module for that subservice. The module name should start with `ietf-service-assurance-`. The namespace of the module should start with `urn:ietf:params:xml:ns:yang:ietf-service-assurance-`. The prefix of the module should start with `sain-`. For instance, the subservice type representing the assurance of a device should have:

\*the name `ietf-service-assurance-device`,

\*the namespace `urn:ietf:params:xml:ns:yang:ietf-service-assurance-device`,

\*and the prefix "sain-device".

The new module should define:

\*A new identity to represent the new type.

\*The parameters fully specifying an instance of the new subservice type.

The new identity should be based on the "subservice-base" identity. The name of the identity should end with "-type", for instance "device-type".

The parameters should be defined in a container named "parameters" augmenting of the choice "/subservices/subservice/parameter" from the main module. The augmentation should be restricted to cases where the type of the subservice matches the identity representing the new service type.

We define two subservice types in the next sections: the "device" subservice type is defined in [Section 5](#) and the "interface" subservice type is defined in [Section 6](#). These subservices can be taken as examples of the rules defined in this section.

Vendors can specify their own subservices types by defining the corresponding modules in their own namespace. An example of such a vendor-specific module is specified in Appendix [Appendix A](#). Vendors can also augment existing IETF-specified subservices to add their own vendor-specific information.

## 5. Subservice Augmentation: `ietf-service-assurance-device` YANG module

### 5.1. Tree View

The following tree diagram [[RFC8340](#)] provides an overview of the "ietf-service-assurance-device" module.

module: `ietf-service-assurance-device`

```
augment /sain:subservices/sain:subservice/sain:parameter:
  +-rw parameters
    +-rw device    string
```

A complete tree view of the base module with all augmenting modules presented in this draft is available in [Appendix B.3](#).

## 5.2. Concepts

As the number of subservices will grow over time, the YANG module is designed to be extensible. A new subservice type requires the precise specifications of its type and expected parameters. Let us illustrate the example of the new device subservice type. As the name implies, it monitors and reports the device health, along with some symptoms in case of degradation.

For our device subservice definition, the new identity "device-type" is specified, as an inheritance from the base identity for subservices. This indicates to the assurance agent that we are now assuring the health of a device.

The typical parameter for the configuration of the device subservice is the name of the device that we want to assure. By augmenting the parameter choice from ietf-service-assurance YANG module for the case of the "device-type" subservice type, this new parameter is specified.

## 5.3. YANG Module

      identifier (e.g. device id, hostname, management IP)
      depends on the context.";
  }
}
}
```

<CODE ENDS>

## 6. Subservice Augmentation: `ietf-service-assurance-interface` YANG module

### 6.1. Tree View

The following tree diagram [[RFC8340](#)] provides an overview of the `ietf-service-assurance-interface` data model.

```
module: ietf-service-assurance-interface

augment /sain:subservices/sain:subservice/sain:parameter:
  +--rw parameters
    +--rw device      string
    +--rw interface  string
```

A complete tree view of the base module with all augmenting modules presented in this draft is available in [Appendix B.3](#).

### 6.2. Concepts

For the interface subservice definition, the new interface-type is specified, as an inheritance from the base identity for subservices. This indicates to the assurance agent that we are now assuring the health of an interface.

The parameters for the configuration of the interface subservice are the name of the device and, on that specific device, a specific interface. These parameters are aligned with the `ietf-interfaces` model described in [[RFC8343](#)] where the name of the interface is the only key needed to identify an interface on a given device. By augmenting the parameter choice from `ietf-service-assurance` YANG module for the case of the interface-type subservice type, those two new parameters are specified.

### 6.3. YANG Module

```
<CODE BEGINS> file "ietf-service-assurance-
interface@2022-08-10.yang"
```

```

module ietf-service-assurance-interface {

}
```

<CODE ENDS>

## 7. Security Considerations

The YANG module specified in this document defines a schema for data that is designed to be accessed via network management protocols such as NETCONF [[RFC6241](#)] or RESTCONF [[RFC8040](#)]. The lowest NETCONF layer is the secure transport layer, and the mandatory-to-implement secure transport is Secure Shell (SSH) [[RFC6242](#)]. The lowest RESTCONF layer is HTTPS, and the mandatory-to-implement secure transport is TLS [[RFC8446](#)].

The Network Configuration Access Control Model (NACM) [[RFC8341](#)] provides the means to restrict access for particular NETCONF or RESTCONF users to a preconfigured subset of all available NETCONF or RESTCONF protocol operations and content.

There are a number of data nodes defined in this YANG module that are writable/ creatable/deletable (i.e., config true, which is the default). These data nodes may be considered sensitive or vulnerable in some network environments. Write operations (e.g., edit-config) to these data nodes without proper protection can have a negative effect on network operations. These are the subtrees and data nodes and their sensitivity/vulnerability:

`*/subservices/subservice` : By modifying this subtree, one can modify the structure of the assurance graph which could alter the status of the services reported by the assurance framework. On one hand, modifications can cause the assurance system to report a service as broken when it is actually healthy (false positive), resulting in engineers or automation software losing time, and potentially cause real issues by doing unnecessary modifications on the network. On the other hand, modifications could prevent the assurance system to report actual issues (false negative), resulting in failures that could have been avoided. Depending on the service, the impact of these avoidable failures could be SLA violations fees or disruption of emergency calls.

Some readable data nodes in this YANG module may be considered sensitive or vulnerable in some network environments. It is thus important to control read access (e.g., via get, get-config, or notification) to these data nodes. These are the subtrees and data nodes and their sensitivity/vulnerability:

`*/subservices/subservice`

`*/agents/agent`

`*/assured-services/assured-service`

Each of these subtrees contains information about services, subservices or possible symptoms raised by the agents. The information contained in this subtree might give information about the underlying network as well as services deployed for the customers. For instance, a customer might be given access to monitor their services status (e.g. via model-driven telemetry). In that example, the customer access should be restricted to nodes representing their services, so as not to divulge information about the underlying network structure or others customers services.

## 8. IANA Considerations

### 8.1. The IETF XML Registry

This document registers 3 URIs in the IETF XML registry [[RFC3688](#)]. Following the format in [[RFC3688](#)], the following registrations are requested:

URI: urn:ietf:params:xml:ns:yang:ietf-service-assurance  
Registrant Contact: The OPSAWG WG of the IETF.  
XML: N/A, the requested URI is an XML namespace.

URI: urn:ietf:params:xml:ns:yang:ietf-service-assurance-device  
Registrant Contact: The OPSAWG WG of the IETF.  
XML: N/A, the requested URI is an XML namespace.

URI: urn:ietf:params:xml:ns:yang:ietf-service-assurance-interface  
Registrant Contact: The OPSAWG WG of the IETF.  
XML: N/A, the requested URI is an XML namespace.

### 8.2. The YANG Module Names Registry

This document registers three YANG modules in the YANG Module Names registry [[RFC7950](#)]. Following the format in [[RFC7950](#)], the following registrations are requested:

name: ietf-service-assurance  
namespace: urn:ietf:params:xml:ns:yang:ietf-service-assurance  
prefix: sain  
reference: RFC XXXX

name: ietf-service-assurance-device  
namespace: urn:ietf:params:xml:ns:yang:ietf-service-assurance-device  
prefix: sain-device  
reference: RFC XXXX

name: ietf-service-assurance-interface  
namespace: urn:ietf:params:xml:ns:yang:ietf-service-assurance-interface  
prefix: sain-interface  
reference: RFC XXXX

All these modules are not maintained by IANA.

## Appendix A. Vendor-specific Subservice Augmentation: example-service-assurance-device-acme YANG module

### A.1. Tree View

The following tree diagram [[RFC8340](#)] provides an overview of the "example-service-assurance-device-acme" module.

```
module: example-service-assurance-device-acme
```

```
augment /sain:subservices/sain:subservice/sain:parameter:
  +-rw parameters
    +-rw device          string
    +-rw acme-specific-parameter  string
```

A complete tree view of the base module with all augmenting modules presented in this draft is available in [Appendix B.3](#).

## **A.2. Concepts**

Under some circumstances, vendor-specific subservice types might be required. As an example of this vendor-specific implementation, this section shows how to augment the "ietf-service-assurance-device" module to add custom support for the device subservice, specific to the ACME Corporation. The specific version adds a new parameter, named "acme-specific-parameter". It's an implementation choice to either derive a new specific identity from the "subservice-base" identity defined in ietf-service-assurance or to augment the parameters from ietf-service-assurance-device, here we choose to create a new identity.

### A.3. YANG Module

```

module example-service-assurance-device-acme {
  yang-version 1.1;
  namespace "urn:example:example-service-assurance-device-acme";
  prefix example-device-acme;

  import ietf-service-assurance {
    prefix sain;
    reference
      "RFC xxxx: YANG Modules for Service Assurance";
  }
  import ietf-service-assurance-device {
    prefix sain-device;
    reference
      "RFC xxxx: YANG Modules for Service Assurance";
  }

  organization
    "IETF OPSAWG Working Group";
  contact
    "WG Web: <https://datatracker.ietf.org/wg/opsawg/>"
    "WG List: <mailto:opsawg@ietf.org>"
    "Author: Benoit Claise <mailto:benoit.claise@huawei.com>"
    "Author: Jean Quilbeuf <mailto:jean.quilbeuf@huawei.com>";
  description
    "This example module extends the ietf-service-assurance-device
    module to add specific support for devices of ACME Corporation. ";

  revision 2022-08-10 {
    description
      "Initial revision";
    reference
      "RFC xxxx: YANG Modules for Service Assurance";
  }

  identity device-acme-type {
    base sain-device:device-type;
    description
      "Network Device is healthy.";
  }

  augment "/sain:subservices/sain:subservice/sain:parameter" {
    when "derived-from-or-self(sain:type, 'device-acme-type)";
    description
      "Augments the parameter choice from ietf-service-assurance
      module with a case specific to the device-acme subservice.";
    container parameters {
      description
        "Parameters for the device-acme subservice type";
      leaf device {

```

```
    type string;
    mandatory true;
    description
        "The device to monitor.";
}
leaf acme-specific-parameter {
    type string;
    mandatory true;
    description
        "The ACME Corporation specific parameter.";
}
}
}
```

## Appendix B. Further Augmentations: IP Connectivity and IS-IS subservices

In this section, we provide two additional YANG modules to completely cover the example in Figure 2 from Section 3.1 of [[I-D.ietf-opsawg-service-assurance-architecture](#)]. The two missing subservice types are IP Connectivity and the Intermediate System to Intermediate System (IS-IS) routing protocol. These modules are presented as examples, some future work is needed to propose a more complete version.

### B.1. IP Connectivity Module Tree View

That subservice represents the unicast connectivity between two IP addresses located on two different devices. Such a subservice could report symptoms such as "No route found". The following tree diagram [[RFC8340](#)] provides an overview of the "example-service-assurance-ip-connectivity" module.

```
module: example-service-assurance-ip-connectivity

augment /sain:subservices/sain:subservice/sain:parameter:
  +--rw parameters
    +--rw device1      string
    +--rw address1    inet:ip-address
    +--rw device2     string
    +--rw address2    inet:ip-address
```

To specify the connectivity that we are interested in, we specify two IP addresses and two devices. The subservice assures that the connectivity between IP address 1 on device 1 and IP address 2 on device 2 is healthy.

### B.2. IS-IS Module Tree View

The following tree diagram [[RFC8340](#)] provides an overview of the "example-service-assurance-is-is" module.

```
module: example-service-assurance-is-is

augment /sain:subservices/sain:subservice/sain:parameter:
  +--rw parameters
    +--rw instance-name  string
```

The parameter of this subservice is the name of the IS-IS instance to assure.

### **B.3. Global Tree View**

The following tree diagram [[RFC8340](#)] provides an overview of the "ietf-service-assurance", "ietf-service-assurance-device", "example-service-assurance-device-acme", "example-service-assurance-ip-connectivity" and "example-service-assurance-is-is" modules.

    "The instance to monitor.";  
  }  
}  
}
```

## Appendix C. Example of YANG instance

This section contains an example of YANG instance that conform to the YANG modules. The validity of this data instance has been checked using [yangson](#). Yangson requires a YANG library [[RFC8525](#)] to define the complete model against which the data instance must be validated. We provide in [Appendix D](#) the JSON library file, named "ietf-service-assurance-library.json", that we used for validation.

We provide below the contents of the file "example\_configuration\_instance.json" which contains the configuration data that models the Figure 2 from Section 3.1 of [[I-D.ietf-opsawg-service-assurance-architecture](#)]. The instance can be validated with yangson by using the invocation "yangson -v example\_configuration\_instance.json ietf-service-assurance-library.json", assuming all the files (YANG and JSON) defined in this draft reside in the current folder.

]
}
}
```

## Appendix E. Changes between revisions

[[RFC editor: please remove this section before publication.]]

v09 - v10

- \*Address comments from Last Call

v07 - v08

- \*Address comments from Rob Wilton's AD review

v06 - v07

- \*Addressed early YANG doctor comments from version -06: changed -  
idty for -type or -base in identity names and removed "under-  
maintenance" leaf

- \*Add new list of services with the corresponding subservices

- \*Remove assurance-graph-version and state the limitations of  
having only the current graph available in the module.

- \*Added new list of agents to store symptom and guarantee unicity  
of symptom ids

- \*Added security consideration for readable nodes

- \*Added section on rejecting circular dependencies

v05 - v06

- \*Remove revision history in modules

- \*Present elements in order of the tree for the main module

- \*Rewriting and rewording for clarity

- \*Made parameters mandatory for the subservices

v04 - v05

- \*Remove Guidelines section

- \*Move informative parts (examples) to appendix

- \*Minor text edits and reformulations

v03 - v04

- \*Fix YANG errors

\*Change is-is and ip-connectivity subservices from ietf to example.

\*Mention that models are NMDA compliant

\*Fix typos, reformulate for clarity

v02 - v03

\*Change counter32 to counter64 to avoid resetting too frequently

\*Explain why relation between health-score and symptom's health-score-weight is not defined and how it could be defined

v01 - v02

\*Explicitly represent the fact that the health-score could not be computed (value -1)

v00 - v01

\*Added needed subservice to model example from architecture draft

\*Added guideline section for naming models

\*Added data instance examples and validation procedure

\*Added the "parameters" container in the interface YANG module to correct a bug.

## **Acknowledgements**

The authors would like to thank Jan Lindblad for his help during the design of these YANG modules. The authors would like to thank Stephane Litkowski, Charles Eckel, Mohamed Boucadair, Tom Petch, Dhruv Dhody and Rob Wilton for their reviews.
