OSPF Link-local Signaling
draft-ietf-ospf-lls-05.txt

Status of this Memo

By submitting this Internet-Draft, each author represents that any applicable patent or other IPR claims of which he or she is aware have been or will be disclosed, and any of which he or she becomes aware will be disclosed, in accordance with [Section 6 of BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF), its areas, and its working groups. Note that other groups may also distribute working documents as Internet-Drafts.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

The list of current Internet-Drafts can be accessed at <http://www.ietf.org/ietf/1id-abstracts.txt>.

The list of Internet-Draft Shadow Directories can be accessed at <http://www.ietf.org/shadow.html>.

This Internet-Draft will expire on October 22, 2008.

Abstract

OSPF is a link-state intra-domain routing protocol. OSPF routers exchange information on a link using packets that follow a well-defined fixed format. The format is not flexible enough to enable new features which need to exchange arbitrary data. This document describes a backward-compatible technique to perform link-local signaling, i.e., exchange arbitrary data on a link.

Table of Contents

1.	Introduction	3

1. Introduction

This document describes an extension to OSPFv2 [[OSPFV2](#)] and OSPFv3 [[OSPFV3](#)] allowing additional information to be exchanged between routers on the same link. OSPFv2 and OSPFv3 packet formats are fixed and do not allow for extension. This document proposes appending an optional data block composed of Type/Length/Value (TLV) triplets to existing OSPFv2 and OSPFv3 packets to carry this additional information. Throughout this document, OSPF will be used when the specification is applicable to both OSPFv2 and OSPFv3. Similarly, OSPFv2 or OSPFv3 will be used when the text is protocol specific.

One potential way of solving this task could be introducing a new packet type. However, that would mean introducing extra packets on the network which may not be desirable and may cause backward compatibility issues. This document describes how to exchange data using standard OSPF packet types.

1.1. Requirements notation

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [[KEY](#)].

2. Proposed solution

To perform link-local signaling (LLS), OSPF routers add a special data block to the end of OSPF packets or right after the authentication data block when cryptographic authentication is used. The length of the LLS block is not included into the length of OSPF packet, but is included in the IPv4/IPv6 packet length. Figure 1 illustrates how the LLS data block is attached.

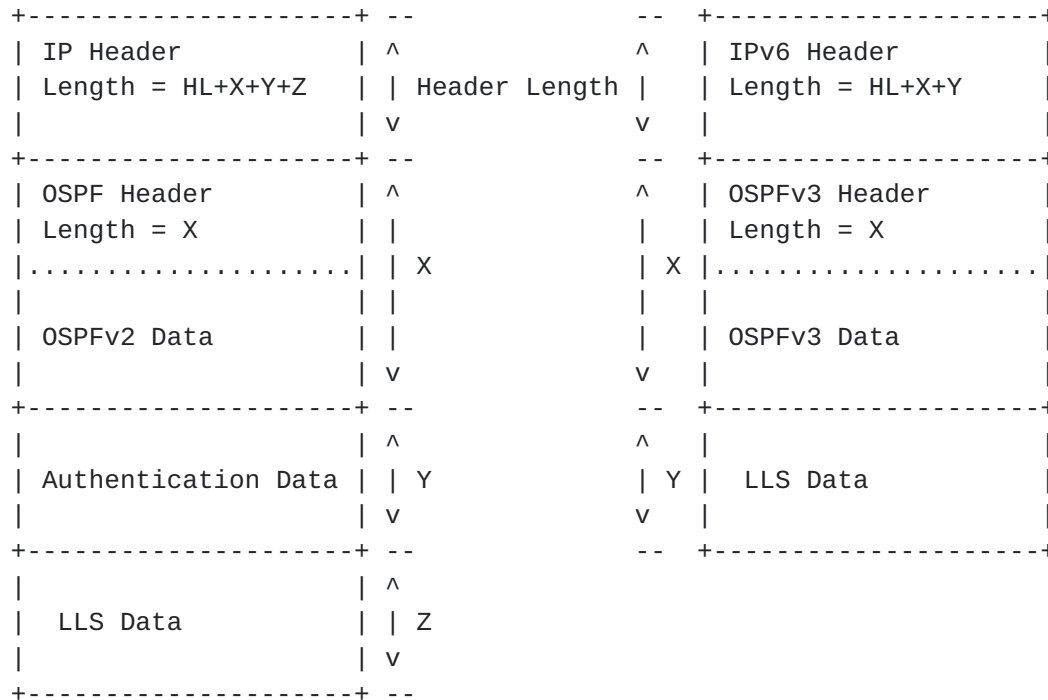

Figure 1: LLS Data Block in OSPFv2 and OSPFv3

The LLS data block MAY be attached to OSPF Hello and DD packets. The data included in LLS block attached to a Hello packet MAY be used for dynamic signaling since Hello packets may be sent at any time in time. However, delivery of LLS data in Hello packets is not guaranteed. The data sent with DD packets is guaranteed to be delivered as part of the adjacency forming process.

This document does not specify how the data transmitted by the LLS mechanism should be interpreted by OSPF routers. As routers that do not understand LLS may receive these packets, changes made due to LLS block TLV's do not affect the basic routing when interacting with non-LLS routers.

2.1. Options Field

A new L bit (L stands for LLS) is introduced to OSPF Options field (see Figure 2a/2b). Routers set the L bit in Hello and DD packets to indicate that the packet contains LLS data block. In other words, LLS data block is only examined if the L bit is set.

```

+---+---+---+---+---+---+---+---+
| * | 0 | DC| L |N/P| MC| E | * |
+---+---+---+---+---+---+---+---+

```

Figure 2a: OSPFv2 Options field

```

      0          1          2
    0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3
+---+---+---+---+---+---+---+---+---+---+---+---+
| | | | | | | | | | | | |L|AF|*|*|DC| R| N|MC| E|V6|
+---+---+---+---+---+---+---+---+---+---+---+---+

```

Figure 2b: OSPFv3 Options field

The L bit is only set in Hello and DD packets.

2.2. LLS Data Block

The data block used for link-local signaling is formatted as described below (see Figure 3 for illustration).

```

      0          1          2          3
    0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1
+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+
|                               |           LLS Data Length           |
+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+
|                               |                                     |
|                               LLS TLVs                               |
|                               |                                     |
.                               .                                     .
.                               .                                     .
.                               .                                     .
+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+

```

Figure 3: Format of LLS Data Block

The Checksum field contains the standard IP checksum for the entire contents of the LLS block.

Bits in the Value field do not have any semantics from the point of view of the LLS mechanism. This field MAY be used to announce some

OSPF capabilities that are link-specific. Also, other OSPF extensions MAY allocate bits in the bit vector to perform boolean link-local signaling.

The length of the Value field in the E0-TLV is 4 bytes.

The value of the type field in the E0-TLV is 1.

The E0-TLV MUST only appear once in the LLS data block.

Figure 5: Format of E0 TLV

Currently, [\[OOB\]](#) and [\[RESTART\]](#) use bits in the Extended Options field of the E0-TLV.

The Extended Options bits are defined in [Section 3](#).

2.5. Cryptographic Authentication TLV (OSPFv2 ONLY)

This document defines a special TLV that is used for cryptographic authentication (CA-TLV) of the LLS data block. This TLV MUST be included in the LLS block when the cryptographic authentication is enabled on the corresponding interface. The message digest of the LLS block MUST be calculated using the same key and authentication algorithm as used for the OSPFv2 packet. The cryptographic sequence number is included in the TLV and MUST be the same as the one in the OSPFv2 authentication data for the LLS block to be considered authentic.

The TLV is constructed as shown in Figure 6.

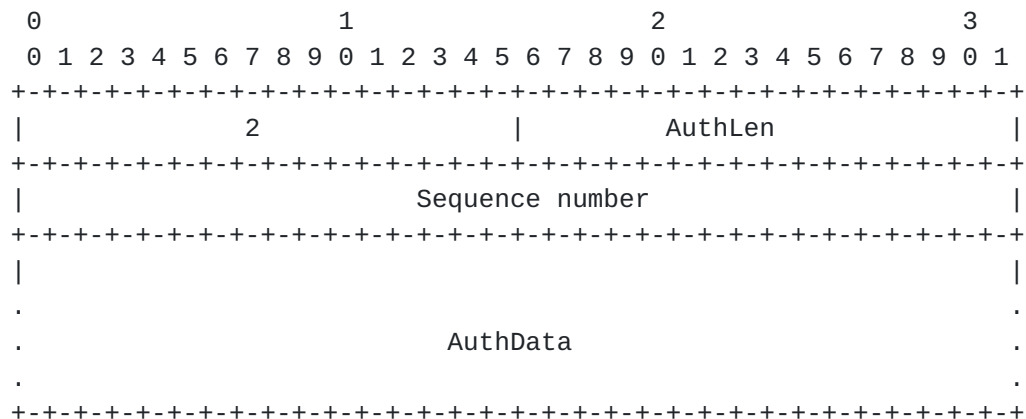

Figure 6: Format of Cryptographic Authentication TLV

The value of the Type field for the CA-TLV is 2.

The Length field in the header contains the length of the data portion of the TLV including 4 bytes for Sequence Number and the length of the message digest block for the whole LLS block in bytes.

The Sequence Number field contains the cryptographic sequence number that is used to prevent simple replay attacks. For the LLS block to be considered authentic, the Sequence Number in the CA-TLV MUST match the Sequence Number in the OSPFv2 packet header Authentication field. In the event of Sequence Number mismatch or Authentication failure, the whole LLS block MUST be ignored.

The AuthData contains the message digest calculated for the LLS data block.

The CA-TLV MUST only appear once in the the LLS block. Also, when present, this TLV SHOULD be the last TLV in the LLS block.

2.6. Private and Experimental TLVs

LLS type values in the range of 32768-65536 are reserved for private and experimental use. The first four octets of the Value field MUST be the private enterprise code [[ENTNUM](#)]. This allows multiple vendor private extensions to coexist in a network.

3. IANA Considerations

LLS TLV types are maintained by the IANA. Extensions to OSPF which require a new LLS TLV type MUST be reviewed by an designated expert from the routing area.

Following the policies outlined in [[IANA](#)], LLS type values in the range of 0-32767 are allocated through an IETF Consensus action and LLS type values in the range of 32768-65536 are reserved for private and experimental use.

This document assigns the following LLS TLV types in OSPFv2/OSPFv3.

TLV Type	Name	Reference
0	Reserved	
1	Extended Options	[RFCNNNN]*
2	Cryptographic Authentication+	[RFCNNNN]*
3-32767	Reserved for assignment by the IANA	
32768-65535	Private Use	

*[RFCNNNN] refers to the RFC number-to-be for this document.

+ Cryptographic Authentication TLV is only defined for OSPFv2

This document also assigns the following bits for the Extended Options bits field in the EO-TLV outlined in [Section 2.5](#):

Extended Options Bit	Name	Reference
0x00000001	LSDB Resynchronization (LR)	[OOB]
0x00000002	Restart Signal (RS-bit)	[RESTART]

Other Extended Options bits will be allocated through an IETF consensus action.

4. Compatibility Issues

The modifications to OSPF packet formats are compatible with standard OSPF since OSPF router not supporting LLS will ignore the LLS data block after the OSPF packet or cryptographic message digest.

5. Security Considerations

The described technique provides the same level of security as OSPFv2 protocol by allowing LLS data to be authenticated using the same cryptographic authentication that OSPFv2 uses (see [Section 2.5](#) for more details).

OSPFv3 utilizes IPsec for authentication and encryption [[OSPFV3AUTH](#)]. With IPsec, the AH (Authentication Header), ESP (Encapsulating Security Payload), or both are applied to the entire OSPFv3 payload including the LLS block.
