COPS usage for RSVP

February 13, 1999

Status of this Memo

This document is an Internet-Draft and is in full conformance with all provisions of [Section 10 of RFC2026](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF), its areas, and its working groups. Note that other groups may also distribute working documents as Internet-Drafts.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

The list of current Internet-Drafts can be accessed at
<http://www.ietf.org/ietf/1id-abstracts.txt>

The list of Internet-Draft Shadow Directories can be accessed at
<http://www.ietf.org/shadow.html>.

Abstract

This document describes usage directives for supporting COPS policy services in RSVP environments.

[Page 2]

1 Introduction

The Common Open Policy Service (COPS) protocol is a query response protocol used to exchange policy information between a network policy server and a set of clients [[COPS](#)]. COPS is being developed within the RSVP Admission Policy Working Group (RAP WG) of the IETF, primarily for use as a mechanism for providing policy-based admission control over requests for network resources [[RAP](#)].

This document is based on and assumes prior knowledge of the RAP framework [[RAP](#)] and the basic COPS [[COPS](#)] protocol. It provides specific usage directives for using COPS in outsourcing policy control decisions by RSVP clients (PEPs) to policy servers (PDPs).

Given the COPS protocol design, RSVP directives are mainly limited to RSVP applicability, interoperability, usage guidelines, as well as client specific examples.

2 RSVP values for COPS objects

The usage of several COPS objects is affected when used for client type RSVP. This section describes these objects and their usage.

2.1 Common Header, client-type

RSVP is COPS client-type 1

2.2 Context Object (Context)

The semantics of the Context object for RSVP is as follows:

R-Type (Request Type Flag)

Incoming-Message request

This context is requested when the PEP receives an incoming RSVP message. The PDP may decide to accept or reject the incoming message and may also apply other decision object to it. If the incoming message is rejected, RSVP should treat it as if it never arrived.

Resource-Allocation request

This context is requested when the PEP is about to commit local resources to an RSVP flow (admission control). This context applies to Resv messages only. The decision whether to commit local resources is performed for the merge of all reservations associated with an RSVP flow, (which have arrived on a particular interface, potentially from several RSVP Next-Hops).

Outgoing-Message request (forwarding an outgoing RSVP message)

This context is requested when the PEP is about to forward an outgoing RSVP message. The PDP may decide to allow or deny

Shai Herzog

Expires August 1999

[Page 3]

the outgoing message, as well as provide an outgoing policy data object.

M-Type (Message Type)

The M-Type field in the Context Object may have one of the following values that correspond to supported RSVP messages in COPS:

- 1 = Path
- 2 = Resv
- 3 = PathErr
- 4 = ResvErr

Note: The PathTear, ResvTear, and the Resv Confirm message types are not supported.

2.3 Client Specific Information (ClientSI)

All objects that were received within an RSVP message are encapsulated inside the Client Specific Information Object (Signaled ClientSI) sent from the PEP to the remote PDP. (See [Section 3.1](#) on multiple flows packed in a single RSVP message).

The PEP and PDP share RSVP state and the PDP is assumed to implement the same RSVP functional specification as the PEP. In the case where a PDP detects the absence of objects required by [\[RSVP\]](#) it should return an <Error> in the Decision message indicating "Mandatory client-specific info missing". If, on the other hand, the PDP detects the absence of optional RSVP objects that are needed to approve the Request against current policies, the PDP should return a negative <Decision>.

Unlike the Incoming and Outgoing contexts, Resource Allocation isn't always directly associated with a specific RSVP message. In a multicast session, it may represent the merging of multiple incoming reservations. Therefore, the ClientSI object should specifically contain the SESSION and STYLE objects along with the merged FLOWSPEC, FILTERSPEC list and SCOPE object (whenever relevant).

Shai Herzog

Expires August 1999

[Page 4]

2.4 Decision Object (Decision)

COPS provide the PDP with flexible controls over the PEP using RSVP's response to messages. While accepting an RSVP message, PDPs may provide preemption priority, trigger warnings, replace RSVP objects, and much more, using Decision Commands, Flags and Objects.

DECISION COMMANDS

Only two commands apply to RSVP

Install

Positive Response:

Accept/Allow/Admit an RSVP message or local resource allocation.

Remove

Negative Response:

Deny/Reject/Remove an RSVP message or local resource allocation.

DECISION FLAGS

The only decision flag that applies to RSVP:

Trigger Error

If this flag is set, RSVP should schedule a PathErr, in response of a Path message, or a ResvErr (in response of a Resv message).

STATELESS POLICY DATA

This object may include one or more policy elements (as specified for the RSVP Policy Data object [[RSVP-EXT](#)]) which are assumed to be well understood by the client's LDP. The PEP should consider these as an addition to the decision already received from the PDP (it can only add, but cannot override it).

For example: Given Policy Elements that specify a flow's preemption priority, these elements may be included in an incoming Resv message or may be also be provided by the PDP responding to a query.

Stateless objects must be well understood, but not necessarily supported by all PEPs. For example, assuming a standard policy element for preemption priority, it is perfectly legitimate for some PEPs not to support such preemption and to ignore it. The PDP must be careful when using such objects, especially, it must be prepared for these objects would be ignored by PEPs.

Stateless Policy Data may be returned in decisions and apply individually to each of the contexts flagged in REQ messages. When applied to Incoming, it is assumed to have been received as a POLICY_DATA object in the incoming message. When applied to Resource

Allocation it is assumed to have been received on all merged incoming messages. Last, when applied to outgoing message it is assumed to have been received in all messages contributing to the outgoing message.

REPLACEMENT DATA

The Replacement object may contain multiple RSVP objects to be replaced (from the original RSVP request). Typical replacement is performed on the Forward Outgoing request (for instance, replacing outgoing Policy Data), but is not limited, and can also be performed on other contexts (such as Resources-Allocation Request). In other cases, replacement of the RSVP FlowSpec object may be useful for controlling resources across a trusted zone (with PIN nodes). Currently, RSVP clients are only required to allow replacement of three objects: POLICY_DATA, ERROR_SPEC, and FLOWSPEC, but could optionally support replacement of more objects.

RSVP object replacement is performed in the following manner:

If Replacement Data decision doesn't appear in a decision message, all signaled objects are processed as if the PDP was not there. When an object of a certain C-Num appears it replaces ALL the instances of C-Num objects in the RSVP message. If it appears empty (with a length of 4) it simply removes all instances of C-Num objects without adding a thing.

3 Operation of COPS for RSVP PEPs

3.1 RSVP flows

Policy Control is performed per RSVP flow, which is defined by the atomic unit of RSVP reservation (TC reservation). Reservation styles may also impact the definition of flows; a set of senders which are considered as a single flow for WF reservation are considered as a set of individual flows when FF style is used.

Multiple FF flows may be packed into a single Resv message. A packed message must be unpack where a separate request is issued for each of the packed flows as if they were individual RSVP messages. Each COPS Request should include the associated POLICY_DATA objects, which are, by default, all POLICY_DATA objects in the packed message. Sophisticated PEPs, capable of looking inside policy objects, may examine the POLICY_DATA or SCOPE object to narrow down the list of associated flows (as optimization).

Please note that the rules governing Packed RSVP message apply equally to Incoming as well as Outgoing REQ context.

3.2 Expected Associations for RSVP Requests

When making a policy decision, the PDP may consider both Resv as well as its matching Path state (associated state). State association is trivial in the common unicast case since the RSVP flow includes one Path state and one Resv state. In multicast cases

this correspondence may be more complicated, as the match may be many to many. The COPS protocol assumes that the PDP is RSVP knowledgeable and capable of determining these associations based on the contents of the Client REQ message and especially the ClientSI object.

For example, the PDP should be able to recognize activation and deactivation of RSVP blockade state following discrete events like the arrival of a ResvErr message (activate the blockade state) as well as the change in the outgoing Resv message.

3.3 RSVP's Capacity Admission Control: Commit and Delete

In RSVP, the admission of a new reservation requires both an administrative approval (policy control) and capacity admission control. After being approved by both, and after the reservation was successfully installed, the PEP notifies the remote PDP by sending a report message specifying the Commit type. The Commit type report message signals when billing should effectively begin and performing heavier delayed operations (e.g., debiting a credit card) is permissible by the PDP.

If instead a PDP approved reservation fails admission due to lack of resources, the PEP must issue a no-commit report and fold back and send an updated request to its previous state (previously installed reservation). If no state was previously installed, the PEP should issue a delete (DRQ).

Shai Herzog

Expires August 1999

[Page 7]

3.4 Policy Control Over PathTear and ResvTear

PathTear and ResvTear messages are not controlled by this policy architecture. This relies on two assumptions: First, that MD-5 authentication verifies that the Tear is received from the same node that sent the initial reservation, and second, that it is functionally equivalent to that node holding-off refreshes for this reservation. When a ResvTear or PathTear is received at the PEP, all affected states installed on the PDP should either be deleted or updated by the PEP.

3.5 PEP Caching COPS Decisions

Because COPS is a stateful protocol, refreshes for RSVP Path and Resv messages need not be constantly sent to the remote PDP. Once a decision has been returned for a request, the PEP can cache that decision and apply it to future refreshes. When the PEP detects a change in the corresponding Resv or Path message, it should update the PDP with the new request-state. PEPs may continue to use the cached state until receiving the PDP response. This case is very different from initial admission of a flow; given that valid credentials and authentication have already been established, the relative long RSVP refresh period, and the short PEP-PDP response time, the tradeoff between expedient updates and attack prevention leans toward expediency. However, this is really a PEP choice, and is irrelevant to PDPs.

If the connection is lost between the PEP and the PDP, the cached RSVP state may be retained for the RSVP timeout period to be used for previously admitted flows (but cannot be applied to new or updated state). If connection can not be reestablished with the PDP or a backup PDP after the timeout period, the PEP is expected to purge all its cached decisions. Without applicable cached decision, the PEP must either reject the flow or resort to its LDP (if available) for decisions.

Once a connection is reestablished to a new (or the original) PDP the PDP may issue a SSQ request. In this case, the PEP must reissue requests that correspond to the current RSVP state (as if all the state has been updated recently). It should also include as LDP the current (cached) decision regarding each such state.

[Page 8]

3.6 Using Multiple Context Flags in a single query

RSVP is a store-and-forward control protocol where messages are processed in three distinctive steps (input, resource allocation, and output). Each step requires a separate policy decision as indicated by context flags (see [Section 2.2](#)). In many cases, setting multiple context flags for bundling two or three operations together in one request may significantly optimize protocol operations.

The following rules apply for setting multiple Context flags:

- a. Multiple context flags can be set only in two generic cases which are guaranteed not to cause ambiguity and represent substantial portion of expected COPS transactions.

Unicast FF:

[Incoming + Allocation + Outgoing]

Multicast with only one Resv message received on the interface

[Incoming + Allocation]

- b. Context events are ordered by time since every message processing must first be processed as Incoming, then as Resource allocation and only then as Outgoing. When multiple context flags are set, all ClientSI objects included in the request are assumed to be processed to the latest flag. This rule applies both to request (REQ) context as well as to decision (DEC) context.

For example: when combining Incoming + Allocation for an incoming Resv message, the flowspec included in the ClientSI would be the one corresponding to the Resource-Allocation context (TC).

- c. Each decision is bound to a context object, which determines which portion of the request context it applies to. When different decisions apply to different sub-groups of context the PDP should send each group of decision objects encapsulated or separated by the context flags object with the context flags applicable to these objects set. (See the examples in [Section 4](#)).

3.7 RSVP Error Reporting

RSVP uses the ERROR_SPEC object in PathErr and ResvErr messages to report policy errors. While the contents of the ERROR_SPEC object is defined in [[RSVP](#), [RSVP-EXT](#)], the PDP is in the best position to provide its contents (sub-codes). This is performed in the following manner: First, the PEP (RSVP) queries the PDP before sending a PathErr or ResvErr, and then the PDP returns the constructed ERROR_SPEC in the Replacement Data Decision Object.

3.8 Security Considerations

Security for RSVP messages is provided by inter-router MD5 authentication [MD5], assuming a chain-of-trust model. A possible deployment scenario calls for PEPs to be deployed at the network edge (boundary nodes) while PINs are deployed in the core of the network (backbone). In this case, MD5 trust (authentication) must be established between boundary (non-neighboring) PEPs. Such PDP-PDP trust can be achieved through internal signing (integrity) of the Policy Data object (see [RSVP-EXT]).

4 Illustrative Examples, Using COPS for RSVP

This section details both typical unicast and multicast scenarios.

4.1 Unicast Flow Example

This section details the steps in using COPS for controlling a Unicast RSVP flow. It details the contents of the COPS messages with respect to the following figure.

Figure 1: Unicast Example: a single PEP view

The PEP router has two interfaces (if1, if2). Sender S1 sends to receiver R1.

A Path message arrives from S1:

```
PEP --> PDP    REQ := <Handle A> <Context: in & out, Path>
                <In-Interface if2> <Out-Interface if1>
                <ClientSI: all objects in Path message>
```

PDP --> PEP DEC := <Handle A> <Context: in & out, Path>
 <Decision: Command, Install>

A Resv message arrives from R1:

```
PEP --> PDP   REQ := <Handle B>
                  <Context: in & allocation & out, Resv>
                  <In-Interface if1> <Out-Interface if2>
                  <ClientSI: all objects in Resv message>
```

```
PDP --> PEP   DEC := <Handle B>
                  <Context: in, Resv>
                  <Decision: command, Install>
                  <Context: allocation, Resv>
                  <Decision: command, Install>
                  <Decision: Stateless, Priority=7>
                  <Context: out, Resv>
                  <Decision: command, Install>
                  <Decision: replacement, POLICY-DATA1>
```

```
PEP --> PDP   RPT := <Handle B>
                  <Report type: commit>
```

Notice that the Decision was split because of the need to specify different decision objects for different context flags.

Time Passes, the PDP changes its decision:

```
PDP --> PEP   DEC := <Handle B>
                  <Context: allocation, Resv>
                  <Decision: command, Install>
                  <Decision: Stateless, Priority=3>
```

Because the priority is too low, the PEP preempts the flow:

```
PEP --> PDP   DRQ := <Handle B>
                  <Reason Code: Preempted>
```

Time Passes, the sender S1 ceases to send Path messages:

```
PEP --> PDP   DRQ := <Handle A>
                  <Reason: Timeout>
```

[Page 11]

4.2 Shared Multicast Flows

This section details the steps in using COPS for controlling a multicast RSVP flow. It details the contents of the COPS messages with respect to the following figure.

Figure 2: Multicast example: a single PEP view

Figure 2 shows an RSVP PEP (router) which has two senders (S1, S2) and three receivers (R1, R2, R3) for the same multicast session. Interface if2 is connected to a shared media. In this example, we assume that the multicast membership is already in place. No previous RSVP messages were received, and the first to arrive is a Path message on interface if3 from sender S1:

```

PEP --> PDP   REQ := <Handle A> <Context: in, Path>
                  <In-interface if3>
                  <ClientSI: all objects in incoming Path>

PDP --> PEP   DEC := <Handle A> <Context: in, Path>
                  <Decision: command, Install>
  
```

The PEP consults its forwarding table, and finds two outgoing interface for the path (if1, if2). The exchange below is for interface if1, another exchange would likewise be completed for if2 using the new handle B2.

Shai Herzog

Expires August 1999

[Page 12]

```
PEP --> PDP   REQ := <Handle B1> <Context: out, Path>
                  <Out-interface if1>
                  <clientSI: all objects in outgoing Path>
```

```
PDP --> PEP   DEC := <Handle B1>
                  <Context: out, Path>
                  <Decision: command, Install>
                  <Decision: Replacement, POLICY-DATA1>
```

Here, the PDP decided to allow the forwarding of the Path message and provided the appropriate policy-data object for interface if1.

Next, a WF Resv message from receiver R2 arrives on interface if2.

```
PEP --> PDP   REQ := <Handle C> <Context: in & allocation, Resv>
                  <In-interface if2>
                  <ClientSI: all objects in Resv message
                  including RSpec1 >
```

```
PDP --> PEP   DEC := <Handle C>
                  <Context: in, Resv>
                  <Decision: command, Install>
                  <Context: allocation, Resv>
                  <Decision: command, Install>
                  <Decision: Stateless, priority=5>
```

```
PEP --> PDP   RPT := <handle C> <Commit>
```

Here, the PDP approves the reservation and assigned it preemption priority of 5. The PEP responded with a commit report.

The PEP needs to forward the Resv message upstream toward S1:

```
PEP --> PDP   REQ := <Handle E> <Context: out, Resv>
                  <out-interface if3>
                  <Client info: all objects in outgoing Resv>
```

```
PDP --> PEP   DEC := <Handle E>
                  <Context: out, Resv>
                  <Decision: command, Install>
                  <Decision: replacement, POLICY-DATA2>
```

Note: The Context object is part of this DEC message even though it may look redundant since the REQ specified only one context flag.

Shai Herzog

Expires August 1999

[Page 13]

Next, a new WF Resv message from receiver R3 arrives on interface if2 with a higher RSpec (RSpec2). Given two reservations arrived on if2, it cannot perform a request with multiple context flags, and must issue them separately.

The PEP re-issues an updated handle C REQ with a new context object <Context: in , Resv>, and receives a DEC for handle C.

```
PEP --> PDP   REQ := <Handle F> <Context: in , Resv>
                <In-interface if2>
                <ClientSI: all objects in Resv message
                including RSpec2 >

PDP --> PEP   DEC := <Handle F> <Context: in , Resv>
                <Decision: command, Install>

PEP --> PDP   REQ := <Handle G> <Context: allocation, Resv>
                <In-interface if2>
                <ClientSI: all objects in merged Resv
                including RSpec2 >

PDP --> PEP   DEC := <Handle G>
                <Context: allocation, Resv>
                <Decision: command, Install>
                <Decision: Stateless, Priority=5>

PEP --> PDP   RPT := <handle G> <Commit>
```

Given the change in incoming reservations, the PEP needs to forward a new outgoing Resv message upstream toward S1. This repeats exactly the previous interaction of Handle E, except that the ClientSI objects now reflect the merging of two reservations.

Shai Herzog

Expires August 1999

[Page 14]

If an ResvErr arrives from S1, the PEP maps it to R3 only (because it has a higher flowspec: Rspec2) the following takes place:

```
PEP --> PDP   REQ := <Handle H> <Context: in, ResvErr>
                <In-interface if3>
                <ClientSI: all objects in incoming ResvErr>

PDP --> PEP   DEC := <Handle H> <Context: in, ResvErr>
                <Decision: command, Install>

PEP --> PDP   REQ := <Handle I> <Context: out, ResvErr>
                <Out-interface if2>
                <ClientSI: all objects in outgoing ResvErr>

PDP --> PEP   DEC := <Handle I>
                <Context: out, ResvErr>
                <Decision: command, Install>
                <Decision: Replacement, POLICY-DATA3>
```

When S2 joins the session by sending a Path message, incoming and outgoing Path requests are issued for the new Path. A new outgoing Resv request would be sent to S2.
