**MPL Forwarder Select (MPLFS)**  
**draft-ietf-roll-mpl-forw-select-00**

**Abstract**

This document describes a Forwarder Selection (MPLFS) protocol for the Multicast Protocol for Low-Power and lossy Networks (MPL) to reduce the density of forwarders such that the number of forwarded messages is reduced.

The protocol uses Trickle to distribute link-local information about the identity of the neighbours of the nodes that have MPL-enabled interfaces. In the end-state all nodes are connected to a minimum number, N\_DUPLICATE, of forwarders, where N\_DUPLICATE is application dependent, and there is a path between any two forwarders.

**Note**

Discussion and suggestions for improvement are requested, and should be sent to [roll@ietf.org](mailto:roll@ietf.org).

**Status of This Memo**

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on June 10, 2017.

## [1.](#) Introduction

The Multicast Protocol for Low-Power and Lossy Networks (MPL) [[RFC7731](#)] is designed for small devices interconnected by a lossy wireless network such as IEEE 802.15.4. A seed sends a multicast message with a realm-local scope, admin-local scope or higher as specified in [[RFC4291](#)].

Forwarders forward these messages with an increasing interval size. When the density of the forwarders is high, the DATA\_MESSAGE\_K (k) parameter stops the retransmission of messages in a given Trickle interval when more than k copies of a message have been received. This mechanism prevents network saturation but leads to difficult to predict end-to-end data transmission delays. For IoT short predictable delays are wanted and the k parameter is set to a large

value. When the density of forwarders is high and  $k$  is large, the message may be forwarded by a high number of forwarders that conflict on the link. With extreme forwarder densities, small Trickle intervals, and  $k$  is infinite, just sending one multicast message may lead to an overload of the communication medium.

The number of forwarded messages can be reduced by selecting a minimal set of forwarders. However, for large networks, manually selecting the forwarders is much work, and changing network conditions and configurations make the manual selection an unwanted burden to the network management.

This document specifies a protocol that selects the forwarders such that each MPL-enabled device is connected to  $N\_DUPLICATE$  forwarders, where  $N\_DUPLICATE > 0$  can be set. The parameter  $N\_DUPLICATE$  determines how much path redundancy there is for each MPL message. The value of  $N\_DUPLICATE$  should be at least 1, because a value of 0 has as result that no forwarder exists in the network during the protocol execution. Moreover, the protocol is distributed and dynamic in nature to face a continuously changing topology.

The protocol is inspired by the work described for NeighbourHood Discovery (NHDP) [[RFC6130](#)] and Simple Multicast Forwarding (SMF) [[RFC6621](#)]. In contrast to the "HELLO" messages described in [[RFC6130](#)], this protocol uses the Trickle protocol [[RFC6206](#)] to multicast link-local messages, containing a CBOR payload [[RFC7049](#)].

A simulation of the protocol has been done for some example topologies. The number of forwarders allocated by the protocol are compared in [Appendix A](#) with the optimum (lowest) number of forwarders for these topologies.

### **1.1. Terminology**

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [[RFC2119](#)].

Readers of this specification should be familiar with all the terms and concepts discussed in [[RFC7731](#)]. The following terms are defined in this document:

synchronization time    The moment that a node can change its state at messages reception.

The following list contains the abbreviations used in this document.

XXXX:    TODO, and others to follow.

## 2. Protocol overview

Nodes participating in MPLFS exchange messages with a format that is described in [Section 6](#). A participating node communicates to all its neighbours with link-local multicast messages as described in [Section 4](#).

Failing links provide a lot of instability. Only messages sent over stable links are accepted. [Section 4](#) describes a mechanism to refuse messages from unstable links.

Each node maintains a set of 1-hop neighbours where each neighbour contains information about its own 1-hop neighbours. On the basis of the contents of the set, the node can decide to become a Forwarder or not, as explained in [Section 5](#).

The protocol never ends, with a minimum frequency of exchanging maintenance messages specified by an interval size of `I_MAX_SELECT`. When the set of links is stable, the protocol stabilizes such that there is a path between any two forwarders, and every MPL-enabled node is connected to at least `N_DUPLICATE` MPL forwarders (when existing), where `N_DUPLICATE > 0`. `N_DUPLICATE` can be set dependent on the application requirements. With `N_DUPLICATE = 2`, it is expected that a multicast message arrives at an intended recipient with very high probability.

Nodes have a state that determines whether they are forwarder or not. The state of a node can only be changed by the node itself. To avoid race conditions, (e.g. two nodes simultaneously decide to be forwarder, while only one is intended) the node with the highest address of all 1-hop neighbours is the only one allowed to change state. Unlike [\[RFC5614\]](#), that considers 3-tuple (Router Priority, MDR Level and Router ID) to allow self state change, this approach only takes into account the node address. Consequently, only k-hop neighbours, with  $k > 2$ , can change state simultaneously, and the 1-hop and 2-hop neighbours of a given node can change state one by one.

## 3. Data sets

Each node, `n_0`, maintains a state with two values: Fixed Forwarder (FF) and No Forwarder (NF). Each node also maintains a set, `S1_0`, containing information about `n_0`'s 1-hop neighbours and `n_0` itself. Each entry, `n_i`, in `S1_0` has the following attributes:

address of `n_i`: the address can be the 64 bit IPv6 address or the short 16 bit address.

average-rssi-in: the average rssi of the messages received by  $n_0$  from  $n_i$ .

average-rssi-out: the average rssi of the messages received by  $n_i$  from  $n_0$ .

nr\_FF: the number of neighbours,  $n_{ij}$ , of  $n_i$  (including  $n_i$ ) with state = FF.

nr\_Under: the number of neighbours,  $n_{ij}$ , of  $n_i$  with nr\_FF < N\_DUPLICATE.

nr\_Above: the number of neighbours,  $n_{ij}$ , of  $n_i$  with nr\_FF > N\_DUPLICATE.

size: the size of  $S1_i$ , the set of 1-hop neighbours of  $n_i$ .

state: the state of  $n_i$ .

#### **4. Neighbor distribution**

A participating node multicasts link-local so-called "neighbour messages" with the Trickle protocol. It uses the multicast address LINK\_LOCAL\_ALL\_NODES as destination. The message sent by  $n_0$  contains the contents of  $S1_0$ . The contents of a "neighbour message" from  $n_i$  received by  $n_0$  is called  $M_i$ . The rssi value associated with the reception of the "neighbour message" is called new\_rssi. The message  $M_i$  contains information about the set  $S1_i$  with the following attributes for all nodes in  $S1_i$ :

- o address
- o average-rssi-in
- o nr\_FF
- o nr\_Under
- o nr\_Above
- o size
- o state

On reception of  $M_i$  from  $n_i$  for the first time, the receiving node adds  $n_i$  to  $S1_0$ , and sets average-rssi-in of  $n_i$  in  $S1_0$  to new\_rssi. For all following messages from  $n_i$ , the average-rssi-in

for  $n_i$  is calculated in the following way:  $\text{average-rssi-in} := (\text{average-rssi-in} * \text{WEIGHT\_AVERAGE} + \text{new\_rssi}) / (\text{WEIGHT\_AVERAGE} + 1)$ .

The neighbour nodes of  $M_i$  are called  $n_{ij}$ . For the  $n_{ij}$  with an address that is equal to the address of  $n_0$ : the value of  $\text{average-rssi-out}$  of  $n_0$  is set equal to the value of  $\text{average-rssi-in}$  of  $n_{ij}$ .

The contents of  $n_0$  is updated with the contents of  $M_i$ . Updating includes the following actions:

- o Add  $n_i$  to  $S1_0$ , if  $n_i$  not present in  $S1_0$ .
- o Set size of  $n_i$  equal to the number of entries in  $M_i$ .
- o When  $n_{ij}.\text{address} = n_j.\text{address}$ , copy the values of  $\text{nr\_Under}$ ,  $\text{nr\_Above}$ ,  $\text{nr\_FF}$ , and state of  $n_{ij}$  to  $n_j$ .

When the  $\text{average-rssi-in}$  and  $\text{average-rssi-out}$  values of  $n_i$  have been averaged over more than  $\text{WEIGHT\_AVERAGE}$  messages, and the averaged RSSI values are smaller than  $\text{MAXIMUM\_RSSI}$ ,  $n_i$  is called "valid".

## 5. Selection Algorithm

The protocol aims at allocating forwarders in the densest part of the network. A dense network is characterized by a high number of neighbours. Therefore, the protocol attempts to assign status FF to the nodes with the highest number of neighbours that have less than  $N\_DUPLICATE$  neighbours with state = FF ( $\text{nr\_FF} < N\_DUPLICATE$ ).

It is required that a path exists between every two forwarders to prevent network partitioning. Therefore, a node can become forwarder iff one of its neighbours is a forwarder. The consequence of this rule is that one so-called "source-forwarder" must be selected by the network administrator. A likely choice for the "source-forwarder" is the border router.

At the start of the selection protocol the node,  $n_0$ , sets its state to No Forwarder (NF). It sets the Trickle timer to its minimum interval,  $I\_MIN\_SELECT$ , and starts multicasting  $M_0$  to its neighbours. Every time entries are added to, or removed from,  $S1_0$ , the Trickle interval timer is set to  $I\_MIN\_SELECT$ .

The executing node,  $n_0$ , calculates the following parameter values:

- o  $\text{max-under}$  is the maximum of the  $\text{nr\_Under}$  attribute of all valid  $n_i$  in  $S1_0$ .

- o `max_address_u` is the maximum of the addresses of valid `n_i` with `nr_Under = max-under`.
- o `max_address_a` is the maximum of the addresses of all valid `n_i`.
- o `connected` is true iff `nr_FF` of all neighbouring forwarders is equal to `nr_FF` of `n_0`.

The information about the state and the `nr_Under` value of the neighbours comes in asynchronously. Time is needed before the state in a node correctly reflects the state changes of the network. A node can change its state when during the reception of messages of all neighbours, the value of `nr_Under` has not changed.

To calculate its new state, `n_0` does the following:

When the state is NF, a neighbour with state = FF exists, and address = `max_address_u`:  
set state to FF.

When the state is FF, `nr_Above = size S1_0`, `connected` is true, and address = `max_address_a`:  
set state to NF.

## 6. CBOR payload

The payload format is `/application/cbor` [[RFC7049](#)]. The contents of the message is a CBOR array (Major type 4) of CBOR arrays composed of neighbour address, rssi value, size of `S1_i`, forwarder state, `nr_FF`, `nr_Under`, and `nr_Above`. Assuming two neighbours, in diagnostic JSON the payload looks like:

```
[  
[address_1, average-rssi-in_1, size_1, state_1,  
  nr_FF_1, nr_Under_1, nr_Above_1],  
[address_2, average-rssi-in_2, size_2, state_2,  
  nr_FF_2, nr_Under_2, nr_Above_2]  
]
```

Figure 1: CBOR payload

## 7. Default parameter values

The following text recommends default values for the MPLFS protocols.

`I_MIN_SELECT = 0,2`; minimum Trickle timer interval.

`I_MAX_SELECT = 10`; maximum Trickle timer interval.

DATA\_MESSAGE\_K > 10; the redundancy constant.

WEIGHT\_AVERAGE = 10; number of values to average rssi.

MAXIMUM\_RSSI = 3; maximum acceptable average rssi value.

N\_DUPLICATE = 2; requested number of MPL forwarder neighbours for every MPL enabled node.

## **8. Acknowledgements**

We are very grateful to Yasuyuki Tanaka for pointing out the missing discussion on k-values.

## **9. Changelog**

Changes from vanderstok version to ietf version 00

- o copied from vanderstok-roll-forw-select-01
- o added discussion on DATA\_MESSAGE\_K
- o compared generated forwarder set with optimal set

## **Appendix A. example forwarder allocations**

The protocol has been simulated with omnet++ on four different network topologies. The value of N\_DUPLICATE is set to two. Each topology is a rectangular grid, where each grid point is occupied by a node. The distance, D, between two horizontal and vertical direct neighbours is the same. The topologies differ in number of grid points and D. A topology of 9x9 grid points shows how the selection criteria of the protocol affect the distribution of the forwarders when the number of edge nodes is small compared to the number of interior nodes. A topology of 3x20 nodes shows the distribution with a majority of edge nodes. Two radio ranges of the link have been selected: (1) a range of 3,5 times D, and (2) a range of 7 times D. The node density of case 2 is four times higher than for case 1. The two example ranges nicely show how the average distance between the forwarders increases with increasing range.

Table 1 shows the comparison results. Column one indicates the grid topology, Columns 2 indicates the radio range, column 3 indicates the number of protocol forwarders as delivered by the simulation, column four indicates the minimum number of forwarders needed to arrive at at least N-DUPLICATE forwarders for all nodes, column five cites the number of nodes.

topology	range	forwarders	optimum	nodes
9x9	3,5 D	10	9	81
9x9	7 D	3	3	81
3x20	3,5 D	8	8	60
3x20	7 D	5	5	60

Table 1: comparison of protocol set size and optimal set

The table gives confidence that for many cases the size of the protocol forwarder set will be close to the size of an optimal set.
