Using Security Posture Assessment to Grant Access to Enterprise Network
                              Resources
                     draft-ietf-sacm-use-cases-00

Abstract

   This memo documents a sampling of use cases for securely aggregating
   configuration and operational data and assessing that data to
   determine an organization's security posture. From these operational
   use cases, we can derive common functional capabilities and
   requirements to guide development of vendor-neutral, interoperable
   standards for aggregating and assessing data relevant to security
   posture.

the Trust Legal Provisions and are provided without warranty as
described in the Simplified BSD License.

Table of Contents

1. Introduction

   Our goal with this document is to improve our agreement on which
   problems we're trying to solve. We need to start with short, simple
   problem statements and discuss those by email and in person. Once we
   agree on which problems we're trying to solve, we can move on to
   propose various solutions and decide which ones to use.

   This document describes example use cases for endpoint posture
   assessment for enterprises. It provides a sampling of use cases for
   securely aggregating configuration and operational data and assessing
   that data to determine the security posture of individual endpoints,
   and, in the aggregate, the security posture of an enterprise.

   These use cases cross many IT security information domains. From
   these operational use cases, we can derive common concepts, common
   information expressions, functional capabilities and requirements to
   guide development of vendor-neutral, interoperable standards for
   aggregating and assessing data relevant to security posture.

   Using this standard data, tools can analyze the state of endpoints,
   user activities and behaviour, and assess the security posture of an
   organization. Common expression of information should enable
   interoperability between tools (whether customized, commercial, or
   freely available), and the ability to automate portions of security
   processes to gain efficiency, react to new threats in a timely
   manner, and free up security personnel to work on more advanced
   problems.

   The goal is to enable organizations to make informed decisions that
   support organizational objectives, to enforce policies for hardening
   systems, to prevent network misuse, to quantify business risk, and to
   collaborate with partners to identify and mitigate threats.

   It is expected that use cases for enterprises and for service
   providers will largely overlap, but there are additional
   complications for service providers, especially in handling
   information that crosses administrative domains.

The output of endpoint posture assessment is expected to feed into
additional processes, such as policy-based enforcement of acceptable
state, verification and monitoring of security controls, and
compliance to regulatory requirements.

2. Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT",
"SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this
document are to be interpreted as described in RFC 2119 [RFC2119].

3. Endpoint Posture Assessment

Endpoint posture assessment involves collecting information about the
posture of a given endpoint. This posture information is gathered
and then published to appropriate data repositories to make collected
information available for further analysis supporting organizational
security processes.

Endpoint posture assessment typically includes:

o Collecting the posture of a given endpoint;

o Making that posture available to the enterprise for further
   analysis and action; and

o Assessing that the endpoint's posture is in compliance with
   enterprise standards and policy.

3.1. Example - Departmental Software Policy Compliance

In order to meet compliance requirements and ensure that corporate
finance information is not revealed improperly, all computers in the
finance department of Example Corporation are required to run only
software contained on an approved list and to be configured to
download and install software patches every night. Each computer is
checked to make sure it complies with this policy whenever it
connects to the network and at least once a day thereafter. These
daily compliance checks assess the posture of each computer and
report on its compliance with policy.

3.2. Main Success Scenario

1. Define a target endpoint to be assessed

2. Select acceptable state policies to apply to the defined target

3. Identify the endpoint being assessed

4. Collect posture attributes from the target

5. Communicate target identity and collected posture to external
    system for evaluation

6. Compare collected posture attributes from the target endpoint
    with expected state values as expressed in acceptable state
    policies

4. Use Cases

The use cases defined in this section support assessing endpoint
posture in an automated manner as described in Section Section 3.
The following sub-sections describe use cases broken out by their
corresponding IT decipline.

4.1. Asset Management

Organizations manage a variety of assets within their enterprise
including: endpoints, the hardware they are composed of, installed
software, hardware/software licenses used, and configurations.

Managing endpoints and the different types of assets that compose
them involves initially discovering and characterizing each asset
instance, and then identify them in a common way. Characterization
may take the form of logical characterization or security
characterization, where logical characterization may include business
context not otherwise related to security, but which may be used as
information in support of decision making later in risk management.

Coverage involves understanding what and how many assets are under
control. Assessing 80% of the enterprise assets is better than
assessing 50% of the enterprise assets.

Getting asset details can be comparatively subtle - if an enterprise
does not have a precise understanding of its assets, then all
acquired data and consequent actions taken based on the data are
considered suspect.

Assessing assets (managed and unmanaged) requires that we have
visibility into the posture of endpoints, the ability to understand
the composition and relationships between different assets types, and
the ability to properly characterize them at the outset and over
time.

The following list details some requisite Asset Management
capabilities:

   o Discover assets in the enterprise

   o Identify and describe assets using a common vocabulary between
      implementations

   o For a given endpoint, understand the composition and relationship
      of its constituent assets

   o Characterize assets according to security and non-security asset
      properties

   o Reconcile asset representations originating from disparate tools

   o Manage asset information throughout the asset's life cycle

4.1.1. Asset Discovery

   Many network management systems periodically test for the presence of
   endpoints or interfaces in a network, including discovering endpoints
   that have suddenly appeared in a network that are not authorized to
   be part of the network. Other approaches can be used to identify new
   endpoints as they connect to the network alowing for authentication
   and authorization to occur dynamically as part of a network access
   control decision. There are many layers of endpoints, and many
   standardized information models for determining endpoints in a
   network.

   These standardized collections include ARP tables [RFC0826],
   Interface tables such as the Interfaces MIB (IF-MIB) [RFC2863] or the
   YANG module ietf-interfaces , Link Layer Discovery tables [RFC2922],
   DHCP tables (Ref:???), and so on.

4.1.2. Asset Identification

   Identifying assets is critical for managing information provided
   about and collected from endpoints. It is important to have stable
   mechanisms for identifying assets over time to allow asset
   information to be correlated. It is often possible to use
   standardized and proprietary identification mechanisms provided by
   hardware and software asset vendors (e.g., CPU identifiers, product
   tags). In some cases these identifiers may be stable for the life of
   the hardware component. In other cases (e.g., MAC addresses), the
   identifier may be mutable within software. Organizationally provided
   identifiers can also be used to identify assets such as those
   provided by hardware and software certificates, and configurable
   identification sources. In other cases it may only be possible to
   identify an asset by the network addressing information it is
   currently using, requiring additional context to correlate asset

   information across multiple network connection sessions. In an
   enterprise context it is often necessary to use multiple
   identification viewpoints for an asset to correlate data generated
   from endpoint, network, and human sources.

   Some standards focus on identifying the hardware and the system
   software. For example, the SYSTEM-MIB [RFC1213] contains a
   description of the endpoint, an authoritative identifier of the type
   of endpoint assigned by the vendor of the endpoint, an administrative
   name for the endpoint, plus the endpoint's contact person, the
   location of the endpoint, system time, and an enumerator that
   identifies the layer of services provided by the endpoint. The
   system description includes the vendor, product type, model number,
   OS version, and networking software version.

   Similar information is available via the YANG module ietf-system .
   This module includes data node definitions for system identification,
   time-of-day management, user management, DNS resolver configuration,
   and some protocol operations for system management.

4.1.3. Endpoint Components and Asset Composition

   It can be important to characterize the components of an endpoint,
   including physical and logical components, and the relationships
   between the components, such as containment of components within
   other components, or mappings between logical entities and the
   physical entities used to instantiate them. The information about
   the physical entities might include manufacturer-assigned serial
   number, manufacture date, an asset identifier for the component, and
   so. Logical entities may be defined, and associated with the
   physical entities using a mapping table.

   Example standardized data models include the ENTITY-MIB [RFC6933] the
   Q-BRIDGE-MIB MIB [RFC4363] and the MIB for Virtual Machines
   Controlled by a Hypervisor .

4.1.4. Asset Characterization

   It is necessary to collect, store, manage, and exchange a variety of
   different asset characteristics that provide additional context that
   is useful to support automated and human decision making as part of
   operational and security processes. Often this information helps to
   bridge automated and human-oriented processes. In many cases it is
   impractical or infeasible to collect specific asset details using
   technical data collection mechanisms.

   Asset characteristics can take many forms depending on the asset
   type.

For hardware assets the following are often useful characteristics:

o Manufacturer

o Production version

o Hardware characteristics (e.g., memory, storage, network
   interfaces)

o End-of-support dates

For software assets the following are often useful characteristics:

o Software version

o Supported hardware platforms

o Metadata identifying: product family, software function, edition,
   licensing

o Other software dependencies

o End-of-support dates

For managed endpoints, hardware, and software the following are often
useful characteristics:

o Owning organization

o Responsible organizations and individuals (e.g., operations,
   security, inventory management)

o Assigned location for physical devices

o Location within network(s)

This information is important to provide additional context for
supporting management of assets using human and automated processes.
For example, it may be possible to automate assessing that an
endpoint is out of compliance with organizational configuration
guidelines, but additional information is needed to determine who to
notify to correct the configuration. Information provided by asset
characterization will enable notifications to be sent, trouble
tickets to be generated, or specific reports to be generated at a
dashboard for a systems administrator.

[TODO: Do we need more document characteristics or more examples?.]

4.1.5. Asset Resources

This type of asset characterization describes the resources of an
endpoint, such as installed software, running software, software
versions, processes, user sessions, devices (processors, disks,
printers, network interfaces, etc.). This might also provides
monitoring of performance and error states for the related resources.

[TODO: Its not clear if this is asset characterization or data
collection. One way to look at asset characterization is that it is
metadata that is provided by humans. Endpoint data collection is
information provided by machines. The previous list looks like it is
better oriented in the "machine" category. Do we want to move these
examples to a different sub-section?]

An example is the HOST-RESOURCES-MIB [RFC2790]

4.1.6. Asset Representation Reconciliation

[TODO: We need to describe here how different asset identification
viewpoints are reconciled (e.g., endpoint vs. network, passive vs.
active]

4.1.7. Asset Life Cycle

[TODO: What do we want to say here?]

4.2. Endpoint Configuration Management

Organizations manage a variety of configurations within their
enterprise including: endpoints, the hardware they are composed of,
installed software, hardware/software licenses used, and
configurations.

Security configuration management (SCM) deals with the configuration
of endpoints, including networking infrastructure devices and
computing hosts. Data will include installed hardware and software,
its configuration, and its use on the endpoint.

[TODO: While some configuration settings might not be considered
security relevant, it is not always possible to draw a clear
distinction between security and non-security settings (e.g., power
saving features). Do we want to make a distinction between security
and non-security configuration settings?]

The following list details some requisite Configuration Management
capabilities:

o [todo]

4.2.1. Organizing Configuration Metadata

Configuration metadata supports tooling helping organizations
understand what configuration they should implement, using specific
configuration values.

Enable data repositories containing machine-represtations of:

  Configuration scoring: Characterizations of the relative security
  value of dsscrete configuration settings and specific values

  Configuration dependencies (e.g., lists of settings, associated
  software, pre-requisite configurations)

  Control catalog mappings supporting compliance [todo: in scope?]

4.2.2. Publishing Recommended Configuration Posture

Provide a mechanism for vendors and organizations to exchange
machine-oriented descriptions of recommended configuration setting
for software products. Enable organizations to apply recommended
settings as expected configuration posture. Enable association of
data-driven collection instructions using appropriate formats.

4.2.3. Defining Organizationally Expected Configuration Posture

Provide a mechanism for organizations to define and exchange expected
configuration posture including: authorized software and associated
configuration settings.

[TODO: Should software installation posture be defined seperately?]

4.2.4. Collecting Endpoint Configuration Posture

Enable collection and exchange of actual configuration posture
including: installed software and values for configured settings.

[TODO: Should collecting software installation posture be defined
seperately?]

4.2.5. Comparing Expected and Actual Configuration Posture

Enable evaluation of actual configuration posture against expected
configuration posture. Generate a machine-oriented description of
conformant and non-conformat posture including software inventory and
configuration values.

[TODO: Should collecting software installation posture be defined seperately?]

[TODO: Examining software version configuration - Example - HOST-RESOURCES-MIB

4.2.6. Examining configuration of logical to physical mappings

[TODO: not sure what this is? Is it in scope?]

Example - ENTITY-MIB

4.2.7. Configuring Endpoint Interfaces

[TODO: not sure what this is? Is it in scope?]

Example - YANG module ietf-interfaces

4.3. Endpoint Posture Change Management

Organizations manage a variety of changes within their enterprise including: [todo]

The following list details some requisite Change Management capabilities:

o [todo]

4.3.1. Defining and Exchanging Baselines

[todo]

4.3.2. Detecting Unauthorized Changes

[todo]

[todo: figure out where these need to go]

4.3.2.1. Endpoint Addressing Changes

Example - DHCP addressing

4.3.2.2. Service Authorization Changes

Example - RADIUS network access

4.3.2.3. Dynamic Resource Assignment Changes

Example - NAT logging

4.3.2.4. Security Authorization Status Changes

Example - SYSLOG Authorization messages. SYSLOG [RFC5424] includes
facilities for security authorization messages. These messages can
be used to alert an analysts that an authorization attempt failed,
and the analyst might choose to follow up and assess potential
attacks on the relevant endpoint.

4.4. Security Vulnerability Management

Vulnerability management involves identifying the patch level of
software installed on the device and the identification of insecure
custom code (e.g. web vulnerabilities). All vulnerabilities need to
be addressed as part of a comprehensive risk management program,
which is a superset of software vulnerabilities. Thus, the
capability of assessing non-software vulnerabilities applicable to
the system is required. Additionally, it may be necessary to support
non-technical assessment of data relating to assets such as aspects
related to operational and management controls.

policy attribute collection

The following list details some requisite Vulnerability Management
capabilities:

o Collect the state of non-technical controls commonly called
   administrative controls (i.e. policy, process, procedure)

o Collect the state of technical controls including, but not
   necessarily limited to:

   * Software inventory (e.g. operating system, applications,
      patches)

   * Configuration settings

4.4.1. Example - NIDS response

1. An organization's Network Intrusion Detection System detects a
suspect packet received by an endpoint and sends an alert to an
analyst. The analyst looks up the endpoint in the asset inventory
database, looks up the configuration policy associated with that
endpoint, and initiates an endpoint assessment of installed software
and patches on the endpoint to determine if the endpoint is compliant
with policy.

The analyst reviews the results of the assessment and takes action according to organization policy and procedures.

4.4.2. Example - Historical vulnerability analysis

When a serious vulnerability or a zero-day attack is discovered, one of the first priorities in any organization is to determine which endpoints may have been affected and assess those endpoints to try to determine whether they were compromised. Checking current endpoint state is not sufficient because an endpoint may have been temporarily compromised due to this vulnerability and then the infection may have removed itself. In fact, the vulnerable software may have been removed or upgraded since the compromise took place. And if the endpoint is still compromised, the malware on the endpoint may cause it to lie about its configuration. In this environment, maintaining historical information about endpoint configuration is essential. Such information can be used to find endpoints that had the vulnerable software installed at some point in time. Those endpoints can be checked for current or past indicators of compromise such as files or behavior linked to a known exploit for this vulnerability. Endpoints found to be vulnerable can be isolated to prevent infection while remediation is done. Endpoints believed to be compromised can be isolated for analysis and to limit the spread of infection.

4.4.3. Source Address Validation

Source Address Validation Improvement methods were developed to prevent nodes attached to the same IP link from spoofing each other's IP addresses, so as to complement ingress filtering with finer-grained, standardized IP source address validation. The framework document describes and motivates the design of the SAVI methods. Particular SAVI methods are described in other documents.

4.5. Data Collection

Central to any automated assessment solution is the ability to collect data from, or related to, an endpoint, such as the security state of the endpoint and its constituent assets.

So, is data collection a requirement or an architectural concept rather than a use case?

QUESTION: Understand more about what is meant by non-software vulnerabilities

4.6. Assessment Result Analysis

The data collected needs to be analyzed for compliance to a standard stipulated by the enterprise. Analysis methods may vary between enterprises, but commonly take a similar form.

The following capabilities support the analysis of assessment results:

o Comparing actual state to expected state

o Scoring/weighting individual comparison results

o Relating specific comparisons to benchmark-level requirements

o Relating benchmark-level requirements to one or more control frameworks

4.7. Content Management

The capabilities required to support risk management state measurement will yield volumes of content. The efficacy of risk management state measurement depends directly on the stability of the driving content, and, subsequently, the ability to change content according to enterprise needs.

Capabilities supporting Content Management should provide the ability to create/define or modify content, as well as store and retrieve said content of at least the following types:

o Configuration checklists

o Assessment rules

o Data collection rules and methods

o Scoring models

o Vulnerability information

o Patch information

o Asset characterization data and rules

Note that the ability to modify content is in direct support of tailoring content for enterprise-specific needs.

5. IANA Considerations

This memo includes no request to IANA.

6. **Security Considerations**

   This memo documents, for Informational purposes, use cases for
   security automation. While it is about security, it does not affect
   security.

7. **Acknowledgements**

   The National Institute of Standards and Technology (NIST) and/or the
   MITRE Corporation have developed specifications under the general
   term "Security Automation" including languages, protocols,
   enumerations, and metrics.

   The authors would like to recognize and thank Adam Montville for his
   work on early edits of this draft. Additionally, the authors would
   like to thank Kathleen Moriarty and Stephen Hanna for contributing
   text to this document. The authors would also like to acknowledge
   the members of the SACM mailing list for their keen and insightful
   feedback on the concepts and text within this document.

8. **Change Log**

8.1. **draft-waltermire-sacm-use-cases-05 to draft-ietf-sacm-use-cases-00**

   o Transitioned from individual I/D to WG I/D based on WG consensus
      call.

   o Fixed a number of spelling errors. Thank you Erik!

   o Added keywords to the front matter.

   o Removed the terminology section from the draft. Terms have been
      moved to: draft-dbh-sacm-terminology-00

   o Removed requirements to be moved into a new I/D.

   o Extracted the functionality from the examples and made the
      examples less prominent.

   o Renamed "Functional Capabilities and Requirements" section to "Use
      Cases".

         Reorganized the "Asset Management" sub-section. Added new text
         throughout.

      + Renamed a few sub-section headings.

      + Added text to the "Asset Characterization" sub-section.

o Renamed "Security Configuration Management" to "Endpoint
   Configuration Management". Not sure if the "security" distinction
   is important.

   * Added new sections, partially integrated existing content.

   * Additional text is needed in all of the sub-sections.

o Changed "Security Change Management" to "Endpoint Posture Change
   Management". Added new skeletal outline sections for future
   updates.

8.2. -04- to -05-

o Are we including user activities and behavior in the scope of this
   work? That seems to be layer 8 stuff, appropriate to an IDS/IPS
   application, not Internet stuff.

o I removed the references to what the WG will do because this
   belongs in the charter, not the (potentially long-lived) use cases
   document. I removed mention of charter objectives because the
   charter may go through multiple iterations over time; there is a
   website for hosting the charter; this document is not the correct
   place for that discussion.

o I moved the discussion of NIST specifications to the
   acknowledgements section.

o Removed the portion of the introduction that describes the
   chapters; we have a table of concepts, and the existing text
   seemed redundant.

o Removed marketing claims, to focus on technical concepts and
   technical analysis, that would enable subsequent engineering
   effort.

o Removed (commented out in XML) UC2 and UC3, and eliminated some
   text that referred to these use cases.

o Modified IANA and Security Consideration sections.

o Moved Terms to the front, so we can use them in the subsequent
   text.

o Removed the "Key Concepts" section, since the concepts of ORM and
   IRM were not otherwise mentioned in the document. This would seem
   more appropriate to the arch doc rather than use cases.

   o Removed role=editor from David Waltermire's info, since there are
      three editors on the document. The editor is most important when
      one person writes the document that represents the work of
      multiple people. When there are three editors, this role marking
      isn't necessary.

   o Modified text to describe that this was specific to enterprises,
      and that it was expected to overlap with service provider use
      cases, and described the context of this scoped work within a
      larger context of policy enforcement, and verification.

   o The document had asset management, but the charter mentioned
      asset, change, configuration, and vulnerability management, so I
      added sections for each of those categories.

   o Added text to Introduction explaining goal of the document.

   o Added sections on various example use cases for asset management,
      config management, change management, and vulnerability
      management.
