Location Source Parameter for the SIP Geolocation Header Field draft-ietf-sipcore-locparam-05

Abstract

There are some circumstances where a Geolocation header field may contain more than one locationValue. Knowing the identity of the node adding the locationValue allows the recipient more freedom in selecting the value to look at first rather than relying solely on the order of the locationValues. This document defines the "loc-src" parameter so that the entity adding the locationValue to Geolocation header field can identify itself using its hostname. This document updates RFC 6442.

Status of This Memo

Updates: 6442 (if approved)

1. Introduction

The SIP Geolocation specification [RFC6442] describes the "Geolocation" SIP header field which is used to indicate that the SIP message is conveying location information. [RFC6442] specifies that SIP intermediaries should not add locationValues to a SIP request that already contains locationValue. [RFC6442] also states that if a SIP intermediary adds location it is fully responsible for addressing the concerns of any 424 (Bad Location Information) SIP response it receives. However, some communications architectures, such as 3GPP [TS23-167] and ETSI [M493], prefer to use information provided by edge proxies or acquired through the use of core-network nodes, before using information provided solely by user equipment (UE). These solutions don't preclude the use of UE-provided location but require a means of being able to distinguish the identity of the node adding the locationValue to the SIP message from that provided by the UE.

[RFC6442] stipulates that the order of locationValues in the Geolocation header field is the same as the order in which they were added to the header field. Whilst this order provides guidance to the recipient as to which values were added to the message earlier in the communication chain, it does not identify which node added the locationValue. Knowing the identity of the entity that added the location to the message allows the recipient to choose which location to consider first rather than relying solely on the order of the locationValues in the Geolocation header field.

This document extends the Geolocation header field of [RFC6442], by allowing an entity adding the locationValue to identity itself using a hostname. This is done by defining a new geoloc-param header field parameter, "loc-src". How the entity adding the locationValue to the header field obtains the location information is out of scope of this document.

2. Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.

3. Rationale

The primary intent of the "loc-src" parameter in this specification is for use in emergency calling. There are various architectures defined for providing emergency calling using SIP-based messaging.

Each has it own characteristics with corresponding pros and cons. All of them allow the UE to provide location information; however, many also attach other sources of location information to support veracity checks, provide backup information, or to be used as the primary location.

This document does not comment on these various architectures or on the rationale for including multiple locationValues. It does recognize that these architectures exist and that there is a need to identify the entity adding the location information.

The "loc-src" parameter adds the location source generating the locationValue to allow recipients to make informed decisions about which of multiple values to use.

The "loc-src" parameter is applicable within a single private administrative domain or between different administrative domains where there is a trust relationship between the domains. Thus it is intended to use this parameter only in trust domains where Spec(T) as described in [RFC3325] exists.

The "loc-src" parameter is not included in a SIP message sent to another network if there is no trust relationship. The "loc-src" parameter is not applicable if the administrative domain manages emergency calls in a way that does not require any generation of the location.

The functional architecture described within ETSI $[\underline{M493}]$ is an example of an architecture where it makes sense to use this parameter.

4. Mechanism

The mechanism adds a geoloc-param parameter to the locationValue defined in $[\mbox{RFC6442}]$ that identifies the hostname of the entity adding the locationValue to the Geolocation header field. The Augmented BNF (ABNF) $[\mbox{RFC5234}]$ for this parameter is shown in Figure 1.

location-source = "loc-src" EQUAL hostname
hostname = <defined in RFC3261>

Figure 1: Location Source

Internet-Draft Location Parameter January 2019

Only a fully qualified host name is valid. The syntax does not support IP addresses, and if an entity conforming to this specification receives a Geolocation header field with a "loc-src" parameter containing an IP address then the parameter MUST be removed.

A SIP intermediary conformant to this specification adding a locationValue to a Geolocation header field SHOULD also add a "loc-src" header field parameter so that it is clearly identified as the node adding the location. A User Agent (UA) MUST NOT insert a "loc-src" header field parameter. If a SIP intermediary receives a message from an untrusted source with the "loc-src" parameter set then it MUST remove the "loc-src" parameter before passing the message into a trusted network.

Example

The following example shows a SIP INVITE message containing a Geolocation header field with two locationValues. The first locationValue points to a PIDF-LO in the SIP body using a content-indirection (cid:) URI per [RFC4483] and this is provided by the UE. The second locationValue is an https URI provided by a SIP intermediary which identifies itself using the "loc-src" parameter.

Figure 2: Example Location Request.

6. Privacy Considerations

This document doesn't change any of the privacy considerations described in [RFC6442]. While the addition of the "loc-src" parameter identifies the entity that added the location in the

signaling path, this addition provides little more exposure than adding a proxy identity to the Record-Route header field.

7. Security Considerations

This document introduces the ability of a SIP intermediary to insert a host name indicating that they added the specific locationValue to the Geolocation header field. The intent is for this field to be used by the location recipient in the event that the SIP message contains multiple locationValues. As a consequence this parameter should only be used by the location recipient in a trusted network.

As already stated in [RFC6442], securing the location hop-by-hop, using TLS, protects the message from eavesdropping and modification in transit, but exposes the information to all SIP intermediaries on the path as well as the endpoint. The "loc-src" parameter is applicable within a single private administrative domain or between different administrative domains where there is a trust relationship between the domains. If such trust domain is not given, it is strongly recommended to delete the location information.

The use of this parameter is not restricted to a specific architecture but using multiple locations and loc-src may end in compatibility issues. [RFC6442] already addresses the issue of multiple locations. To avoid problems with misinterpretation of the "loc-src" parameter, the value may be removed when passed to another domain.

8. IANA Considerations

8.1. Registration of loc-src parameter for Geolocation header field

The IANA is asked to add a new SIP header field parameter for the Geolocation header field in the "Header Field Parameters and Parameter Values" subregistry (created by [RFC3968]) of the "Session Initiation Protocol (SIP) Parameters" registry found at https://www.iana.org/assignments/sip-parameters/.

Header Field: Geolocation

Parameter Name: loc-src

Predefined Values: No

Reference: this RFC

9. Acknowledgements

The authors would like to thank Dale Worley, Christer Holmberg and Jean Mahoney for their extensive review of the draft. The authors would like to acknowledge the constructive feedback provided by Paul Kyzivat and Robert Sparks.
