The WebSocket Protocol as a Transport for the Session Initiation Protocol (SIP)
draft-ietf-sipcore-sip-websocket-06

Abstract

   The WebSocket protocol enables two-way realtime communication between
   clients and servers. This document specifies a new WebSocket sub-
   protocol as a reliable transport mechanism between SIP (Session
   Initiation Protocol) entities to enable usage of SIP in new
   scenarios. This document normatively updates RFC 3261.

Status of this Memo

   This Internet-Draft is submitted in full conformance with the
   provisions of BCP 78 and BCP 79.

   Internet-Drafts are working documents of the Internet Engineering
   Task Force (IETF). Note that other groups may also distribute
   working documents as Internet-Drafts. The list of current Internet-
   Drafts is at http://datatracker.ietf.org/drafts/current/.

   Internet-Drafts are draft documents valid for a maximum of six months
   and may be updated, replaced, or obsoleted by other documents at any
   time. It is inappropriate to use Internet-Drafts as reference
   material or to cite them other than as "work in progress."

   This Internet-Draft will expire on May 10, 2013.

Table of Contents

1. Introduction

The WebSocket [RFC6455] protocol enables message exchange between
clients and servers on top of a persistent TCP connection (optionally
secured with TLS [RFC5246]). The initial protocol handshake makes
use of HTTP [RFC2616] semantics, allowing the WebSocket protocol to
reuse existing HTTP infrastructure.

Modern web browsers include a WebSocket client stack complying with
the WebSocket API [WS-API] as specified by the W3C. It is expected
that other client applications (those running in personal computers
and devices such as smartphones) will also make a WebSocket client
stack available. The specification in this document enables usage of
SIP in these scenarios.

This specification defines a new WebSocket sub-protocol (as defined
in section 1.9 in [RFC6455]) for transporting SIP messages between a
WebSocket client and server, a new reliable and message boundary
transport for SIP, new DNS NAPTR [RFC3403] service values and
procedures for SIP entities implementing the WebSocket transport.
Media transport is out of the scope of this document.

Section 3 in this specification relaxes the requirement in [RFC3261]
by which the SIP server transport MUST add a "received" parameter in
the top Via header in certain circumstances.

2. Terminology

All diagrams, examples, and notes in this specification are non-
normative, as are all sections explicitly marked non-normative.
Everything else in this specification is normative.

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT",
"SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this
document are to be interpreted as described in [RFC2119].

2.1. Definitions

SIP WebSocket Client: A SIP entity capable of opening outbound
     connections to WebSocket servers and communicating using the
     WebSocket SIP sub-protocol as defined by this document.

SIP WebSocket Server: A SIP entity capable of listening for inbound
     connections from WebSocket clients and communicating using the
     WebSocket SIP sub-protocol as defined by this document.

3. **The WebSocket Protocol**

   This section is non-normative.

   The WebSocket protocol [RFC6455] is a transport layer on top of TCP
   (optionally secured with TLS [RFC5246]) in which both client and
   server exchange message units in both directions. The protocol
   defines a connection handshake, WebSocket sub-protocol and extensions
   negotiation, a frame format for sending application and control data,
   a masking mechanism, and status codes for indicating disconnection
   causes.

   The WebSocket connection handshake is based on HTTP [RFC2616] and
   utilizes the HTTP GET method with an "Upgrade" request. This is sent
   by the client and then answered by the server (if the negotiation
   succeeded) with an HTTP 101 status code. Once the handshake is
   completed the connection upgrades from HTTP to the WebSocket
   protocol. This handshake procedure is designed to reuse the existing
   HTTP infrastructure. During the connection handshake, client and
   server agree on the application protocol to use on top of the
   WebSocket transport. Such application protocol (also known as a
   "WebSocket sub-protocol") defines the format and semantics of the
   messages exchanged by the endpoints. This could be a custom protocol
   or a standardized one (as the WebSocket SIP sub-protocol defined in
   this document). Once the HTTP 101 response is processed both client
   and server reuse the underlying TCP connection for sending WebSocket
   messages and control frames to each other. Unlike plain HTTP, this
   connection is persistent and can be used for multiple message
   exchanges.

   WebSocket defines message units to be used by applications for the
   exchange of data, so it provides a message boundary-preserving
   transport layer. These message units can contain either UTF-8 text
   or binary data, and can be split into multiple WebSocket text/binary
   transport frames as needed by the WebSocket stack.

      The WebSocket API [WS-API] for web browsers only defines callbacks
      to be invoked upon receipt of an entire message unit, regardless
      of whether it was received in a single Websocket frame or split
      across multiple frames.

4. **The WebSocket SIP Sub-Protocol**

   The term WebSocket sub-protocol refers to an application-level
   protocol layered on top of a WebSocket connection. This document
   specifies the WebSocket SIP sub-protocol for carrying SIP requests
   and responses through a WebSocket connection.

4.1. Handshake

The SIP WebSocket Client and SIP WebSocket Server negotiate usage of
the WebSocket SIP sub-protocol during the WebSocket handshake
procedure as defined in section 1.3 of [RFC6455]. The Client MUST
include the value "sip" in the Sec-WebSocket-Protocol header in its
handshake request. The 101 reply from the Server MUST contain "sip"
in its corresponding Sec-WebSocket-Protocol header.

Below is an example of a WebSocket handshake in which the Client
requests the WebSocket SIP sub-protocol support from the Server:

```
GET / HTTP/1.1
Host: sip-ws.example.com
Upgrade: websocket
Connection: Upgrade
Sec-WebSocket-Key: dGhlIHNhbXBsZSBub25jZQ==
Origin: http://www.example.com
Sec-WebSocket-Protocol: sip
Sec-WebSocket-Version: 13
```

The handshake response from the Server accepting the WebSocket SIP
sub-protocol would look as follows:

```
HTTP/1.1 101 Switching Protocols
Upgrade: websocket
Connection: Upgrade
Sec-WebSocket-Accept: s3pPLMBiTxaQ9kYGzzhZRbK+xOo=
Sec-WebSocket-Protocol: sip
```

Once the negotiation has been completed, the WebSocket connection is
established and can be used for the transport of SIP requests and
responses. The WebSocket messages transmitted over this connection
MUST conform to the negotiated WebSocket sub-protocol.

4.2. SIP encoding

WebSocket messages can be transported in either UTF-8 text frames or
binary frames. SIP [RFC3261] allows both text and binary bodies in
SIP requests and responses. Therefore SIP WebSocket Clients and SIP
WebSocket Servers MUST accept both text and binary frames.

5. SIP WebSocket Transport

5.1. General

WebSocket [RFC6455] is a reliable protocol and therefore the SIP
WebSocket sub-protocol defined by this document is a reliable SIP
transport. Thus, client and server transactions using WebSocket for
transport MUST follow the procedures and timer values for reliable
transports as defined in [RFC3261].

Each SIP message MUST be carried within a single WebSocket message,
and a WebSocket message MUST NOT contain more than one SIP message.
Because the WebSocket transport preserves message boundaries, the use
of the Content-Length header in SIP messages is optional when they
are transported using the WebSocket sub-protocol.

   This simplifies parsing of SIP messages for both clients and
   servers. There is no need to establish message boundaries using
   Content-Length headers between messages. Other SIP transports,
   such as UDP and SCTP [RFC4168] also provide this benefit.

5.2. Updates to RFC 3261

5.2.1. Via Transport Parameter

Via header fields in SIP messages carry a transport protocol
identifier. This document defines the value "WS" to be used for
requests over plain WebSocket connections and "WSS" for requests over
secure WebSocket connections (in which the WebSocket connection is
established using TLS [RFC5246] with TCP transport).

The updated augmented BNF (Backus-Naur Form) [RFC5234] for this
parameter is the following (the original BNF for this parameter can
be found in [RFC3261], which was then updated by [RFC4168]):

```
   transport  =  "UDP" / "TCP" / "TLS" / "SCTP" / "TLS-SCTP"
                 / "WS" / "WSS"
                 / other-transport
```

5.2.2. SIP URI Transport Parameter

This document defines the value "ws" as the transport parameter value
for a SIP URI [RFC3986] to be contacted using the SIP WebSocket sub-
protocol as transport.

The updated augmented BNF (Backus-Naur Form) for this parameter is
the following (the original BNF for this parameter can be found in
[RFC3261], which was then updated by [RFC4168]):

```
transport-param  =  "transport="
                    ( "udp" / "tcp" / "sctp" / "tls" / "ws"
                    / other-transport )
```

5.2.3. Via received parameter

[RFC3261] section 18.2.1 "Receiving Requests" states the following:

> When the server transport receives a request over any transport,
> it MUST examine the value of the "sent-by" parameter in the top
> Via header field value. If the host portion of the "sent-by"
> field contains a domain name, or if it contains an IP address that
> differs from the packet source address, the server MUST add a
> "received" parameter to that Via header field value. This
> parameter MUST contain the source address from which the packet
> was received.

The requirement of adding the "received" parameter does not fit well
into the WebSocket protocol design. The WebSocket connection
handshake reuses existing HTTP infrastructure in which there could be
an unknown number of HTTP proxies and/or TCP load balancers between
the SIP WebSocket Client and Server, so the source address the server
would write into the Via "received" parameter would be the address of
the HTTP/TCP intermediary in front of it. This could reveal
sensitive information about the internal topology of the Server's
network to the Client.

Given the fact that SIP responses can only be sent over the existing
WebSocket connection, the Via "received" parameter is of little use.
Therefore, in order to allow hiding possible sensitive information
about the SIP WebSocket Server's network, this document updates
[RFC3261] section 18.2.1 by stating:

> When a SIP WebSocket Server receives a request it MAY decide not
> to add a "received" parameter to the top Via header. Therefore
> SIP WebSocket Clients MUST accept responses without such a
> parameter in the top Via header regardless the Via "sent-by" field
> contains a domain name.

5.2.4. SIP transport implementation requirements

[RFC3261] section 18 "Transport" states the following:

> All SIP elements MUST implement UDP and TCP. SIP elements MAY
> implement other protocols.

The specification of this new transport enables SIP to be used as a
session establishment protocol in scenarios where none of other

transport protocols defined for SIP can be used. Since some
environments do not enable SIP elements to use UDP and TCP as SIP
transport protocols, a SIP element acting as a SIP WebSocket Client
is not mandated to implement support of UDP and TCP and thus MAY just
implement the WebSocket transport defined by this specification.

5.3. Locating a SIP Server

[RFC3263] specifies the procedures which should be followed by SIP
entities for locating SIP servers. This specification defines the
NAPTR service value "SIP+D2W" for SIP WebSocket Servers that support
plain WebSocket connections and "SIPS+D2W" for SIP WebSocket Servers
that support secure WebSocket connections.

   At the time this document was written, DNS NAPTR/SRV queries could
   not be performed by commonly available WebSocket client stacks (in
   JavaScript engines and web browsers).

In the absence of DNS SRV resource records or an explicit port, the
default port for a SIP URI using the "sip" scheme and the "ws"
transport parameter is 80, and the default port for a SIP URI using
the "sips" scheme and the "ws" transport parameter is 443.

6. Connection Keep Alive

This section is non-normative.

It is RECOMMENDED that SIP WebSocket Clients and Servers keep their
WebSocket connections open by sending periodic WebSocket "Ping"
frames as described in [RFC6455] section 5.5.2.

   The WebSocket API [WS-API] does not provide a mechanism for
   applications running in a web browser to control whether or not
   periodic WebSocket "Ping" frames are sent to the server. The
   implementation of such a keep alive feature is the decision of
   each web browser manufacturer and may also depend on the
   configuration of the web browser.

A future WebSocket protocol extension providing a similar keep alive
mechanism could also be used.

The SIP stack in the SIP WebSocket Client MAY also use a Network
Address Translation (NAT) keep-alive mechanism defined for SIP
connection-oriented transports, such as the CRLF Keep-Alive Technique
mechanism described in [RFC5626] section 3.5.1 or [RFC6223].

   Implementing this technique would involve sending a WebSocket
   message to the SIP WebSocket Server with a content consisting of
   only a double CRLF, and expecting a WebSocket message from the
   server containing a single CRLF as response.

7. Authentication

   This section is non-normative.

   Prior to sending SIP requests, a SIP WebSocket Client connects to a
   SIP WebSocket Server and performs the connection handshake. As
   described in Section 3 the handshake procedure involves a HTTP GET
   method request from the Client and a response from the Server
   including an HTTP 101 status code.

   In order to authorize the WebSocket connection, the SIP WebSocket
   Server MAY inspect any Cookie [RFC6265] headers present in the HTTP
   GET request. For many web applications the value of such a Cookie is
   provided by the web server once the user has authenticated themselves
   to the web server, which could be done by many existing mechanisms.
   As an alternative method, the SIP WebSocket Server could request HTTP
   authentication by replying to the Client's GET method request with a
   HTTP 401 status code. The WebSocket protocol [RFC6455] covers this
   usage in section 4.1:

      If the status code received from the server is not 101, the
      WebSocket client stack handles the response per HTTP [RFC2616]
      procedures, in particular the client might perform authentication
      if it receives 401 status code.

   Regardless of whether the SIP WebSocket Server requires
   authentication during the WebSocket handshake, authentication MAY be
   requested at SIP protocol level. Therefore it is RECOMMENDED that a
   SIP WebSocket Client implements HTTP Digest [RFC2617] authentication
   as stated in [RFC3261].

8. Examples

8.1. Registration

```
Alice     (SIP WSS)     proxy.example.com
  |                         |
  |HTTP GET (WS handshake) F1    |
  |---------------------------->|
  |101 Switching Protocols F2    |
  |<----------------------------|
  |                         |
  |REGISTER F3              |
  |---------------------------->|
  |200 OK F4                |
  |<----------------------------|
  |                         |
```

Alice loads a web page using her web browser and retrieves JavaScript
code implementing the WebSocket SIP sub-protocol defined in this
document. The JavaScript code (a SIP WebSocket Client) establishes a
secure WebSocket connection with a SIP proxy/registrar (a SIP
WebSocket Server) at proxy.example.com. Upon WebSocket connection,
Alice constructs and sends a SIP REGISTER request including Outbound
and GRUU support. Since the JavaScript stack in a browser has no way
to determine the local address from which the WebSocket connection
was made, this implementation uses a random ".invalid" domain name
for the Via header sent-by parameter and for the hostport of the URI
in the Contact header (see Appendix A.1).

Message details (authentication and SDP bodies are omitted for
simplicity):

F1 HTTP GET (WS handshake) Alice -> proxy.example.com (TLS)

GET / HTTP/1.1
Host: proxy.example.com
Upgrade: websocket
Connection: Upgrade
Sec-WebSocket-Key: dGhlIHNhbXBsZSBub25jZQ==
Origin: https://www.example.com
Sec-WebSocket-Protocol: sip
Sec-WebSocket-Version: 13

F2 101 Switching Protocols proxy.example.com -> Alice (TLS)

HTTP/1.1 101 Switching Protocols
Upgrade: websocket
Connection: Upgrade
Sec-WebSocket-Accept: s3pPLMBiTxaQ9kYGzzhZRbK+xOo=
Sec-WebSocket-Protocol: sip

9. Security Considerations

9.1. Secure WebSocket Connection

   It is recommended that the SIP traffic transported over a WebSocket
   communication be protected by using a secure WebSocket connection

(using TLS [RFC5246] over TCP).

9.2. Usage of SIPS Scheme

The SIPS scheme in a SIP URI dictates that the entire request path to
the target be secure. If such a path includes a WebSocket connection
it MUST be a secure WebSocket connection.

10. IANA Considerations

10.1. Registration of the WebSocket SIP Sub-Protocol

This specification requests IANA to register the WebSocket SIP sub-
protocol under the "WebSocket Subprotocol Name" Registry with the
following data:

Subprotocol Identifier: sip

Subprotocol Common Name: WebSocket Transport for SIP (Session
   Initiation Protocol)

Subprotocol Definition: TBD: this document

10.2. Registration of new NAPTR service field values

This document defines two new NAPTR service field values (SIP+D2W and
SIPS+D2W) and requests IANA to register these values under the
"Registry for the Session Initiation Protocol (SIP) NAPTR Resource
Record Services Field". The resulting entries are as follows:

Services Field	Protocol	Reference
SIP+D2W	WS	TBD: this document
SIPS+D2W	WS	TBD: this document

10.3. SIP/SIPS URI Parameters Sub-Registry

This specification requests IANA to add a reference to this document
under the "SIP/SIPS URI Parameters" Sub-Registry within the "Session
Initiation Protocol (SIP) Parameters" Registry:

Parameter Name	Predefined Values	Reference
transport	Yes	[RFC3261][TBD: this document]

10.4. Header Fields Sub-Registry

This specification requests IANA to add a reference to this document
under the "Header Fields" Sub-Registry within the "Session Initiation
Protocol (SIP) Parameters" Registry:

```
Header Name    compact   Reference
-----------    -------   ---------
Via            v         [RFC3261][TBD: this document]
```

10.5. Header Field Parameters and Parameter Values Sub-Registry

This specification requests IANA to add a reference to this document
under the "Header Field Parameters and Parameter Values" Sub-Registry
within the "Session Initiation Protocol (SIP) Parameters" Registry:

```
                                 Predefined
Header Field   Parameter Name   Values   Reference
------------   --------------   ------   ---------
Via            received         No       [RFC3261][TBD: this document]
```

11. Acknowledgements

Special thanks to the following people who participated in
discussions on the SIPCORE and RTCWEB WG mailing lists and
contributed ideas and/or provided detailed reviews (the list is
likely to be incomplete): Hadriel Kaplan, Paul Kyzivat, Adam Roach,
Ranjit Avasarala, Xavier Marjou, Nataraju A. B.

Special thanks to Alan Johnston, Christer Holmberg and Salvatore
Loreto for their full reviews, and also to Saul Ibarra Corretge for
his contribution and suggestions.

Special thanks to Kevin P. Fleming for his complete grammatical
review along with suggestions, comments and improvements.

Appendix A. Implementation Guidelines

This section is non-normative.

Let us assume a scenario in which the users access with their web
browsers (probably behind NAT) an application provided by a server on
an intranet, login by entering their user identifier and credentials,
and retrieve a JavaScript application (along with the HTML)
implementing a SIP WebSocket Client.

Such a SIP stack connects to a given SIP WebSocket Server (an
outbound SIP proxy which also implements classic SIP transports such
as UDP and TCP). The HTTP GET method request sent by the web browser
for the WebSocket handshake includes a Cookie [RFC6265] header with
the value previously provided by the server after the successful
login procedure. The Cookie value is then inspected by the WebSocket
server to authorize the connection. Once the WebSocket connection is
established, the SIP WebSocket Client performs a SIP registration to
a SIP registrar server that is reachable through the proxy. After
registration, the SIP WebSocket Client and Server exchange SIP
messages as would normally be expected.

This scenario is quite similar to ones in which SIP UAs behind NATs
connect to a proxy and must reuse the same TCP connection for
incoming requests (because they are not directly reachable by the
proxy otherwise). In both cases, the SIP UAs are only reachable
through the proxy they are connected to.

The SIP Outbound extension [RFC5626] seems an appropriate solution
for this scenario. Therefore these SIP WebSocket Clients and the SIP
registrar implement both the Outbound and Path [RFC3327] extensions,
and the SIP proxy acts as an Outbound Edge Proxy (as defined in
[RFC5626] section 3.4).

SIP WebSocket Clients in this scenario receive incoming SIP requests via the SIP WebSocket Server they are connected to. Therefore, in some call transfer cases the usage of GRUU [RFC5627] (which should be implemented in both the SIP WebSocket Clients and SIP registrar) is valuable.

   If a REFER request is sent to a third SIP user agent including the
   Contact URI of a SIP WebSocket Client as the target in its
   Refer-To header field, such a URI will be reachable by the third
   SIP UA only if it is a globally routable URI. GRUU (Globally
   Routable User Agent URI) is a solution for those scenarios, and
   would cause the incoming request from the third SIP user agent to
   be sent to the SIP registrar, which would route the request to the
   SIP WebSocket Client via the Outbound Edge Proxy.

A.1. SIP WebSocket Client Considerations

The JavaScript stack in web browsers does not have the ability to discover the local transport address used for originating WebSocket connections. Therefore the SIP WebSocket Client constructs a domain name consisting of a random token followed by the ".invalid" top-level domain name, as stated in [RFC2606], and uses it within its Via and Contact headers.

   The Contact URI provided by SIP UAs requesting (and receiving)
   Outbound support is not used for routing requests to those UAs,
   thus it is safe to set a random domain in the Contact URI
   hostport.

Both the Outbound and GRUU specifications require a SIP UA to include a Uniform Resource Name (URN) in a "+sip.instance" parameter of the Contact header they include their SIP REGISTER requests. The client device is responsible for generating or collecting a suitable value for this purpose.

   In web browsers it is difficult to generate or collect a suitable
   value to be used as a URN value from the browser itself. This
   scenario suggests that value is generated according to [RFC5626]
   section 4.1 by the web application running in the browser the
   first time it loads the JavaScript SIP stack code, and then it is
   stored as a Cookie within the browser.

A.2. SIP WebSocket Server Considerations

The SIP WebSocket Server in this scenario behaves as a SIP Outbound Edge Proxy, which involves support for Outbound [RFC5626] and Path [RFC3327].

The proxy performs Loose Routing and remains in the path of dialogs
as specified in [RFC3261]. If it did not do this, in-dialog requests
would fail since SIP WebSocket Clients make use of their SIP
WebSocket Server in order to send and receive SIP messages.
