SR Replication Segment for Multi-point Service Delivery
draft-ietf-spring-sr-replication-segment-06

Abstract

This document describes the SR Replication segment for Multi-point service delivery. A SR Replication segment allows a packet to be replicated from a Replication Node to downstream nodes.

Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC 2119](#) [[RFC2119](#)].

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <https://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on 28 April 2022.

[1.](#) Introduction

We define a new type of segment for Segment Routing [[RFC8402](#)], called Replication segment, which allows a node (henceforth called as Replication Node) to replicate packets to a set of other nodes (called Downstream Nodes) in a Segment Routing Domain. Replication segments provide building blocks for Point-to-Multipoint Service delivery via SR Point-to-Multipoint (SR P2MP) policy. A Replication segment can replicate packet to directly connected nodes or to downstream nodes (without need for state on the transit routers). This document focuses on the Replication segment building block. The use of one or more stitched Replication segments constructed for SR P2MP Policy tree is specified in [[I-D.ietf-pim-sr-p2mp-policy](#)].

[2.](#) Replication Segment

In a Segment Routing Domain, a Replication segment is a logical construct which connects a Replication Node to a set of Downstream Nodes. A Replication segment is a local segment instantiated at a Replication node. It can be either provisioned locally on a node or programmed by a PCE. Replication segments apply equally to both SR-MPLS and SRv6 instantiations of Segment Routing.

A Replication segment is identified by the tuple <Replication-ID, Node-ID>, where:

- * Replication-ID: An identifier for a Replication segment that is unique in context of the Replication Node.
- * Node-ID: The address of the Replication Node that the Replication segment is for. Note that the root of a multi-point service is also a Replication Node.

In simplest case, Replication-ID can be a 32-bit number, but it can be extended or modified as required based on specific use of a Replication segment. When the PCE signals a Replication segment to its node, the <Replication-ID, Node-ID> tuple identifies the segment. Examples of such signaling and extension are described in [\[I-D.ietf-pim-sr-p2mp-policy\]](#).

A Replication segment includes the following elements:

- * Replication SID: The Segment Identifier of a Replication segment. This is a SR-MPLS label or a SRv6 SID [\[RFC8402\]](#).
- * Downstream Nodes: Set of nodes in Segment Routing domain to which a packet is replicated by the Replication segment.
- * Replication State: See below.

The Downstream Nodes and Replication State of a Replication segment can change over time, depending on the network state and leaf nodes of a multi-point service that the segment is part of.

Replication SID identifies the Replication segment in the forwarding plane. At a Replication node, the Replication SID is the equivalent of Binding SID [[I-D.ietf-spring-segment-routing-policy](#)] of a Segment Routing Policy.

Replication State is a list of replication branches to the Downstream Nodes. In this document, each branch is abstracted to a <Downstream Node, Downstream Replication SID> tuple.

In a branch tuple, <Downstream Node> represents the reachability from the Replication Node to the Downstream Node. In its simplest form, this MAY be specified as an interface or nexthop if downstream node is adjacent to the Replication Node. The reachability may be specified in terms of Flex-Algo path (including the default algo) [[I-D.ietf-lsr-flex-algo](#)], or specified by an SR explicit path represented either by a SID-list (of one or more SIDs) or by a Segment Routing Policy [[I-D.ietf-spring-segment-routing-policy](#)].

A packet is steered into a Replication segment at a Replication Node in two ways:

- * When the Active Segment [[RFC8402](#)] is a locally instantiated Replication SID
- * By the root of a multi-point service based on local configuration outside the scope of this document.

In either case, the packet is replicated to each Downstream node in the associated Replication state.

If a Downstream Node is an egress (aka leaf) of the multi-point service, i.e. no further replication is needed, then that leaf node's Replication segment will not have any Replication State and the operation is NEXT. At an egress node, the Replication SID MAY be used to identify that portion of the multi-point service. Notice that the segment on the leaf node is still referred to as a Replication segment for the purpose of generalization.

A node can be a bud node, i.e. it is a Replication Node and a leaf node of a multi-point service at the same time [[I-D.ietf-pim-sr-p2mp-policy](#)].

[2.1.](#) SR-MPLS data plane

When the Active Segment is a Replication SID, the processing results in a POP operation and lookup of the associated Replication state. For each replication in the Replication state, the operation is a PUSH of the downstream Replication SID and an optional segment list on to the packet which is forwarded to the Downstream node. For leaf nodes the inner packet is forwarded as per local configuration.

When the root of a multi-point service steers a packet to a Replication segment, it results in a replication to each Downstream node in the associated replication state. The operation is a PUSH of the replication SID and an optional segment list on to the packet which is forwarded to the downstream node.

[2.2.](#) SRv6 data plane

In SRv6 [[RFC8986](#)], the "Endpoint with replication" behavior (End.Replicate for short) replicates a packet and forwards the packet according to a Replication state.

When processing a packet destined to a local Replication-SID, the packet is replicated to Downstream nodes and/or locally delivered off tree (when this is a bud/leaf node) according to the associated replication state. For replication, the outer header is re-used, and the Downstream Replication SID is written into the outer IPv6 header destination address. If required, an optional segment list may be used on some branches using H.Encaps.Red (while some other branches may not need that). Note that this H.Encaps.Red is independent from the replication segment - it is just used to steer the replicated traffic on a traffic engineered path to a Downstream node.

The above also applies when the Replication segment is for the Root node, whose upstream node has placed the Replication-SID in the header. A local application (e.g. MVPN/EVPN) may also apply H.Encaps.Red and then steer the resulting traffic into the segment. Again note that the H.Encaps.Red is independent of the Replication

segment - it is the action of the application (e.g. MVPN/EVPN service). If the service is on a Root node, the two H.Encaps mentioned, one for the service and other in the previous paragraph for replication to Downstream node SHOULD be combined for optimization (to avoid extra IPv6 encapsulation).

For the local delivery on a bud/leaf node, the action associated with Replication-SID is "look at next SID in SRH". The next SID could be a SID with End.DT2/4/6 local behavior (equivalent of MVPN/EVPN PMSI label in case of tunnel sharing across multiple VPNs). There may also not be a next SID (e.g. MVPN/EVPN with one tunnel per VPN), in which case the Replication-SID is then equivalent to End.DT2/4/6. Note that decapsulation is not an inherent action of a Replication segment even on a bud/leaf node.

3. Use Cases

In the simplest use case, a single Replication segment includes the root node of a multi-point service and the egress/leaf nodes of the service as all the Downstream Nodes. This achieves Ingress Replication [RFC7988] that has been widely used for MVPN [RFC6513] and EVPN [RFC7432] BUM (Broadcast, Unknown and Multicast) traffic.

Replication segments can also be used as building blocks for replication trees when Replication segments on the root, intermediate Replication Nodes and leaf nodes are stitched together to achieve efficient replication. That is specified in [I-D.ietf-pim-sr-p2mp-policy].

4. IANA Considerations

This document requires registration of End.Replicate behavior in "SRv6 Endpoint Behaviors" sub-registry of "Segment Routing Parameters" top-level registry.

```
+====+====+====+====+====+====+====+====+====+====+
| Value | Hex | Endpoint behavior | Reference |
+====+====+====+====+====+====+====+====+====+====+
```

| | | | | |
|---------|---------|---------------|-----------|---------|
| TBD | TBD | End.Replicate | [This.ID] | |
| +-----+ | +-----+ | +-----+ | +-----+ | +-----+ |

Table 1: IETF - SRv6 Endpoint Behaviors

[5.](#) Security Considerations

There are no additional security risks introduced by this design.

[6.](#) Acknowledgements

The authors would like to acknowledge Siva Sivabalan, Mike Koldychev, Vishnu Pavan Beeram, Alexander Vainshtein, Bruno Decraene and Joel Halpern for their valuable inputs.

[Appendix A](#). Illustration of a Replication Segment

This section illustrates an example of a single Replication segment. Examples showing Replication segment stitched together to form P2MP tree (based on SR P2MP policy) are in [[I-D.ietf-pim-sr-p2mp-policy](#)].

Consider the following topology:

Figure 1: Figure 1

[A.1.](#) SR-MPLS

In this example, the Node-SID of a node R_n is $N\text{-SID}_n$ and Adjacency-SID from node R_m to node R_n is $A\text{-SID}_{mn}$. Interface between R_m and R_n is L_{mn} .

Assume a Replication segment identified with $R\text{-ID}$ at Replication Node R_1 and downstream Nodes R_2 , R_6 and R_7 . The Replication SID at node n is $R\text{-SID}_n$. A packet replicated from R_1 to R_7 has to traverse R_4 .

The Replication segment state at nodes R_1 , R_2 , R_6 and R_7 is shown below. Note nodes R_3 , R_4 and R_5 do not have state for the Replication segment.

Replication segment at R_1 :

```

Replication segment <R-ID,R1>:
  Replication SID: R-SID1
  Replication State:
    R2: <R-SID2->L12>
    R6: <N-SID6, R-SID6>
    R7: <N-SID4, A-SID47, R-SID7>
  
```

Replication to R_2 steers packet directly to R_2 on interface L_{12} . Replication to R_6 , using $N\text{-SID}_6$, steers packet via IGP shortest path to that node. Replication to R_7 is steered via R_4 , using $N\text{-SID}_4$ and then adjacency SID $A\text{-SID}_{47}$ to R_7 .

Replication segment at R_2 :

```

Replication segment <R-ID,R2>:
  Replication SID: R-SID2
  Replication State:
    R2: <Leaf>
  
```

Replication segment at R_6 :

Internet-Draft

SR Replication Segment

October 2021

Replication segment <R-ID,R6>:

Replication SID: R-SID6

Replication State:

R6: <Leaf>

Replication segment at R7:

Replication segment <R-ID,R7>:

Replication SID: R-SID7

Replication State:

R7: <Leaf>

When a packet is steered into the Replication segment at R1:

- * Since R1 is directly connected to R2, R1 performs PUSH operation with just <R-SID2> label for the replicated copy and sends it to R2 on interface L12. R2, as Leaf, performs NEXT operation, pops R-SID2 label and delivers the payload.
- * R1 performs PUSH operation with <N-SID6, R-SID6> label stack for the replicated copy to R6 and sends it to R2, the nexthop on IGP shortest path to R6. R2 performs CONTINUE operation on N-SID6 and forwards it to R3. R3 is the penultimate hop for N-SID6; it performs penultimate hop popping, which corresponds to the NEXT operation and the packet is then sent to R6 with <R-SID6> in the label stack. R6, as Leaf, performs NEXT operation, pops R-SID6 label and delivers the payload.
- * R1 performs PUSH operation with <N-SID4, A-SID47, R-SID7> label stack for the replicated copy to R7 and sends it to R2, the nexthop on IGP shortest path to R4. R2 is the penultimate hop for N-SID4; it performs penultimate hop popping, which corresponds to the NEXT operation and the packet is then sent to R4 with <A-SID47, R-SID1> in the label stack. R4 performs NEXT operation, pops A-SID47, and delivers packet to R7 with <R-SID7> in the label stack. R7, as Leaf, performs NEXT operation, pops R-SID7 label and delivers the payload.

For SRv6 , we use SID allocation scheme, reproduced below, from Illustrations for SRv6 Network Programming [[I-D.filsfils-spring-srv6-net-pgm-illustration](#)]

- * 2001:db8::/32 is an IPv6 block allocated by a RIR to the operator
- * 2001:db8:0::/48 is dedicated to the internal address space

Voyer, Ed., et al.

Internet-Draft

SR Replication Segment

October 2021

- * 2001:db8:cccc::/48 is dedicated to the internal SRv6 SID space
- * We assume a location expressed in 64 bits and a function expressed in 16 bits
- * Node k has a classic IPv6 loopback address 2001:db8::k/128 which is advertised in the IGP
- * Node k has 2001:db8:cccc:k::/64 for its local SID space. Its SIDs will be explicitly assigned from that block
- * Node k advertises 2001:db8:cccc:k::/64 in its IGP
- * Function :1:: (function 1, for short) represents the End function with PSP support
- * Function :Cn:: (function Cn, for short) represents the End.X function from to Node n

Each node k has:

- * An explicit SID instantiation 2001:db8:cccc:k:1::/128 bound to an End function with additional support for PSP
- * An explicit SID instantiation 2001:db8:cccc:k:Cj::/128 bound to an End.X function to neighbor J with additional support for PSP
- * An explicit SID instantiation 2001:db8:cccc:k:Fk::/128 bound to an End.Replcate function

Assume a Replication segment identified with R-ID at Replication Node R1 and downstream Nodes R2, R6 and R7. The Replication SID at node

k, bound to an End.Replcate function, is 2001:db8:cccc:k:Fk::/128. A packet replicated from R1 to R7 has to traverse R4.

The Replication segment state at nodes R1, R2, R6 and R7 is shown below. Note nodes R3, R4 and R5 do not have state for the Replication segment.

Replication segment at R1:

Replication segment <R-ID,R1>:

Replication SID: 2001:db8:cccc:1:F1::0

Replication State:

R2: <2001:db8:cccc:2:F2::0->L12>

R6: <2001:db8:cccc:6:F6::0>

R7: <2001:db8:cccc:4:C7::0, 2001:db8:cccc:7:F7::0>

Replication to R2 steers packet directly to R2 on interface L12. Replication to R6, using 2001:db8:cccc:6:F6::0, steers packet via IGP shortest path to that node. Replication to R7 is steered via R4, using End.X SID 2001:db8:cccc:4:C7::0 at R4 to R7.

Replication segment at R2:

Replication segment <R-ID,R2>:

Replication SID: 2001:db8:cccc:2:F2::0

Replication State:

R2: <Leaf>

Replication segment at R6:

Replication segment <R-ID,R6>:

Replication SID: 2001:db8:cccc:6:F6::0

Replication State:

R6: <Leaf>

Replication segment at R7:

Replication segment <R-ID,R7>:

Replication SID: 2001:db8:cccc:7:F7::0

Replication State:

R7: <Leaf>

When a packet, (A,B2), is steered into the Replication segment at R1:

- * Since R1 is directly connected to R2, R1 creates encapsulated replicated copy (2001:db8::1, 2001:db8:cccc:2:F2::0) (A, B2), and sends it to R2 on interface L12. R2, as Leaf, removes outer IPv6 header and delivers the payload.
- * R1 creates encapsulated replicated copy (2001:db8::1, 2001:db8:cccc:6:F6::0) (A, B2) then forwards the resulting packet on the shortest path to 2001:db8:cccc:6::/64. R2 and R3 forward the packet using 2001:db8:cccc:6::/64. R6, as Leaf, removes outer IPv6 header and delivers the payload.
- * R1 creates encapsulated replicated copy (2001:db8::1, 2001:db8:cccc:4:C7::0) (2001:db8:cccc:7:F7::0; SL=1) (A, B2) and sends it to R2, the nexthop on IGP shortest path to 2001:db8:cccc:4::/64. R2 forwards packet to R4 using 2001:db8:cccc:4::/64. R4 executes End.X function on 2001:db8:cccc:4:C7::0, performs PSP action, removes SRH and sends resulting packet (2001:db8::1, 2001:db8:cccc:7:F7::0) (A, B2) to R7. R7, as Leaf, removes outer IPv6 header and delivers the payload.
