Generic Policy Data Model for Simplified Use of Policy Abstractions (SUPA) draft-ietf-supa-generic-policy-data-model-01

### Abstract

This document defines two YANG policy data modules. The first is a generic policy model that is meant to be extended on an application-specific basis. The second is an exemplary extension of the first generic policy model, and defines rules as event-condition-action policies. Both models are independent of the level of abstraction of the content and meaning of a policy.

#### Status of this Memo

This Internet-Draft is submitted in full conformance with the provisions of  $\underline{\mathsf{BCP}}$  78 and  $\underline{\mathsf{BCP}}$  79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <a href="http://datatracker.ietf.org/drafts/current/">http://datatracker.ietf.org/drafts/current/</a>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on April 3, 2017.

## 1. Overview

This document defines two YANG [RFC6020] [RFC6991] policy data models. The first is a generic policy model that is meant to be extended on an application-specific basis. It is derived from the Generic Policy Information Model (GPIM) defined in [1]. The second is an exemplary extension of the first (generic policy) model, and defines policy rules as event-condition-action tuples. Both models are independent of the level of abstraction of the content and meaning of a policy.

The GPIM defines a common framework as a set of model elements (e.g., classes, attributes, and relationships) that specify a common set of policy management concepts that are independent of the type of policy (e.g., imperative, procedural, declarative, or otherwise). The first YANG data model is a translation of the GPIM to a YANG module. The ECA Policy Rule Information Model (EPRIM), also defined in [1], extends the GPIM to represent policy rules that use the Event-Condition-Action (ECA) paradigm. The second YANG data model maps the EPRIM to YANG. The second YANG data model MAY be used to augment the functionality of the first YANG data model.

## 2. Conventions Used in This Document

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119]. In this document, these words will appear with that interpretation only when in ALL CAPS. Lower case uses of these words are not to be interpreted as carrying [RFC2119] significance.

## **3**. Terminology

This section defines acronyms, terms, and symbology used in the rest of this document.

### 3.1. Acronyms

CNF	Conjunctive Normal Form
DNF	Disjunctive Normal Form
ECA	Event-Condition-Action
EPRIM	(SUPA) ECA Policy Rule Information Model $[1]$
FQDN	Fully Qualified Domain Name
FQPN	Fully Qualified Path Name
GPIM	(SUPA) Generic Policy Information Model $[1]$
GUID	Globally Unique IDentifier
NETCONF	Network Configuration protocol
OAM&P	Operations, Administration, Management, and Provisioning
0CL	Object Constraint Language {2] [3]
OID	Object IDentifier
SUPA	Simplified Use of Policy Abstractions
UML	Unified Modeling Language
URI	Uniform Resource Identifier
UUID	Universally Unique IDentifier

## 3.2. Definitions

Action: a set of activities that have a set of associated behavior.

Boolean Clause: a logical statement that evaluates to either TRUE or FALSE. Also called Boolean Expression.

Condition: a set of attributes, features, and/or values that are to be compared with a set of known attributes, features, and/or values in order to make a decision. A Condition, when used in the context of a Policy Rule, is used to determine whether or not the set of Actions in that Policy Rule can be executed or not.

A constraint is a limitation or restriction. Constraints may be added to any type of object (e.g., events, conditions, and actions in Policy Rules).

Halpern, et al. Expires April 3, 2017 [Page 3]

Data Model: a data model is a representation of concepts of interest to an environment in a form that is dependent on data repository, data definition language, query language, implementation language, and protocol (typically one or more of these). This definition is taken from [1].

ECA: Event - Condition - Action (a type of policy).

Event: an Event is defined as any important occurrence in time in the system being managed, and/or in the environment of the system being managed. An Event may represent the changing or maintaining of the state of a managed object. An Event, when used in the context of a Policy Rule, is used to determine whether the Condition clause of an imperative (i.e., ECA) Policy Rule can be evaluated or not.

## FQPN (FUlly Qualified Path Name)

The specification of a path to a file in a system that unambiguously resolves to only that specific file. In this sense, "fully qualified" is independent of context. However, in a distributed system, it may be dependent on the specific format of an operating system. Hence, implementations should consider such issues before allowing the use of FQPNs.

Information Model: an information model is a representation of concepts of interest to an environment in a form that is independent of data repository, data definition language, query language, implementation language, and protocol. This definition is taken from [1].

Metadata: metadata is data that provides descriptive and/or prescriptive information about the object(s) to which it is associated. This enables structure and content of the object(s) to which it applies, as well as usage and other information, to be represented in an extensible manner. It avoids "burying" common information in specific classes, and increases reuse.

SUPAPolicy: A SUPAPolicy is, in this version of this document, an ECA policy rule that MUST contain an ECA policy rule, SHOULD contain one or more SUPAPolicyMetadata objects, and MAY contain other elements that define the semantics of the policy rule. An ECA Policy Rule MUST contain an event clause, a condition clause, and an action clause. Policies are generically defined as a means to monitor and control the changing and/or maintaining of the state of one or more managed objects. This definition is based on the definition of SUPAPolicy in [1].

## 3.3. Symbology

The following representation is used to describe YANG data modules defined in this draft.

- o Brackets "[" and "]" enclose list keys.
- o Abbreviations before data node names: "rw" means configuration data (read-write), and "ro" means state data (read-only).
- o Symbols after data node names: "?" means an optional node, "!" means a presence container, and "\*" denotes a list and leaf-list.
- o Parentheses enclose choice and case nodes, and case nodes are also marked with a colon (":").
- o Ellipsis ("...") stands for contents of subtrees that are not shown.

## 4. Design of the SUPA Policy Data Models

This section describes the design philosophy of the YANG data model, and how they will be maintained.

## 4.1. Objectives

These Data Models are derived from the SUPA Generic Policy Information Model [1]. The overall objective is to faithfully transform that information model into a YANG data model that can be used for communicating policy. The policy scope to be covered is that defined by [1]; please refer to it for more details and background information.

This model is an extensible framework that is independent of the implementation approach for storing polices, as well as being independent of the content and meaning of specific policies. These models can be extended (generally by using the groupings here and defining additional containers for concrete classes) to represent domain- and/or application-specific policies. The ECA model in this document is an example of extending the general policy model towards specific policies.

By using this approach, different policy models will use common semantics, enabling them to be more easily integrated.

One of the important goals of this work is for the semantics of these models to align with those of the generic policy information model. Thus, most of this model was generate by a quasi-algorithmic transformation of the information model. This was done by hand. Certain changes were made to reflect the fact that this is a YANG data model, and therefore, does not need to generically allow for all data modelling languages. Details of the process are described below in section 4.3.

## 4.2 Yang Data Model maintenance

All model changes should be done to both the information model and the data model in parallel. Care is being taken during development of this model to ensure that is the case.

In general, structural changes will be applied to both the information model and the data model, and then any necessary YANG repairs taken to preserve the validity of the YANG data model.

#### 4.3 YANG Data Model Overview

This YANG data model is generated by applying suitable YANG constructs to represent the information in the information model.

There are three key information modeling concepts that this data model needs to represent consistently. These are classes, class inheritance (also known as subclassing) and associations. The SUPA generic policy information model [1] makes extensive use of these concepts.

Each class in the model is represented by a YANG identity and by a YANG grouping. The use of groupings enables us to define these classes abstractly. Each grouping begins with two leaves (either defined in the grouping or inherited via a using clause), which provide common functionality. One leaf is used for the system-wide unique identifier for this instance. This is either named supa-policy-ID (for the SUPAPolicyObject tree, which contains everything EXCEPT metadata objects) or supa-policy-metadata-id (for the SUPAPolicyMetadata tree, which ONLY contains metadata). All associations use supa-policy-IDs. The second leaf is always called the entity-class. It is an identityref which is set to the identity of the instance. The default value for this leaf is always correctly defined by the grouping. It is read-write in the YANG formalism due to restrictions on the use of MUST clauses.

Class inheritance (or subclassing) is done by defining an identity and a grouping for the new class. The identity is based on the parent identity, and is given a new name to represent this class. The new grouping uses the parent grouping. It refines the

entity-class of the parent, replacing the default value of the entity-class with the correct value for this class.

Halpern, et al. Expires April 3, 2017 [Page 6]

Associations are represented by the use of instance-identifiers and association classes. Association classes are classes, using the above construction, which contain leaves representing the set of instance-identifiers for each end of the association, along with any other properties the information model assigns to the association. The two associated classes each have a leaf with an instance-identifier that points to the association class instance. Each instance-identifier leaf is defined with a must clause. That must clause references the entity-class of the target of the instance-identifier, and specifies that the entity class type must be the same as, or subclassed from, a specific named class. Thus, associations can point to any instance of a selected class, or any instance of any subclass of that target.

While not mandated by the YANG, it is expected that the xpath for the instance-identifier will end with an array selection specifying the supa-policy-ID or supa-policy-metadata-id of the target. This enables us to construct the abstract class tree, with inheritance and associations. It is noted and accepted that this process does lose the distinction between containment, association, and aggregation used by the information model.

The concrete class tree is constructed as follows. The YANG model defines a container for each class that is defined as concrete by the information model. That container contains a single list, keyed by either the supa-policy-id or the supa-policy-metadata-id. The content of the list is defined by a uses clause referencing the grouping that defines the class. After this was done, certain additional modifications were made. Specifically, any information model constructs intended to represent lists of possible values were recast as YANG enumerations. Where these lists are used more than once, they are factored out into reusable enumerations.

Certain attributes that are not needed in the YANG (e.g., to represent the range of choices different data models might use for policy identification) were removed for simplicity and clarity.

## 4.4. YANG Tree Diagram

The YANG Tree Diagram starts on the next page. It uses the following abbreviations for datatypes:

- B: Boolean
- E: enumeration
- II: instance-identifier
- IR: identityref
- PC: policy-constraint-language-list
- PD: policy-data-type-encoding-list
- S: string

- YD: yang:date-and-time

- UI: uint32

# 5. SUPA Policy Data Model YANG Module

The SUPA YANG data model module is divided into two main parts:

- 1) a set of containers that represent the objects that make updated a Policy Rule and its Policy Rule Components
- 2) a set of containers that represent the objects that define and apply metadata to Policy Rules and/or Policy Rule Components

[Editor's note] < This will be finished in version 02 >

// Identities are used in this model as a means to provide simple
// introspection to allow an instance-identifier to be tested as to
// what class it represents. This allows must clauses to specify
// that the target of a particular instance-identifier leaf must be a
// specific class, or within a certain branch of the inheritance tree.
// This depends upon the ability to refine the entity class default
// value. The entity class should be read-only. However, as this is
// the target of a MUST condition, it cannot be config-false. Also,
// it appears that we cannot put a MUST condition on its definition,
// as the default (actual) value changes for each inherited object.

             Semantic Versioning Specification [6] as follows:
               <major>.<minor>.<patch>[<pre-release>][<build-metadata>]
            where the first three components (major, minor, and patch)
            MUST be present, and the latter two components (pre-release
             and build-metadata) MAY be present. A version number MUST
             take the form <major>.<minor>.<patch>, where <major>,
             <minor>, and <patch> are each non-negative integers that
            MUST NOT contain leading zeros. In addition, the value of
             each of these three elements MUST increase numerically.
             In this approach, supaVersionMajor denotes a new release;
             supaVersionMinor denotes a minor release; supaVersionPatch
             denotes a version that consists ONLY of bug fixes. Version
             precedence MUST be calculated by separating the version
             into major, minor, patch, and pre-release identifiers, in
             that order. See [1] for more information.";
