Transport Layer Security Protocol Compression Methods
draft-ietf-tls-compression-00.txt

Status of this Memo

This document is an Internet-Draft and is in full conformance with all provisions of [Section 10 of RFC2026](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF), its areas, and its working groups. Note that other groups may also distribute working documents as Internet-Drafts.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

The list of current Internet-Drafts can be accessed at <http://www.ietf.org/ietf/lid-abstracts.txt>.

The list of Internet-Draft Shadow Directories can be accessed at <http://www.ietf.org/shadow.html>.

This Internet-Draft will expire on March 6, 2003.

Abstract

The Transport Layer Security (TLS) protocol ([RFC 2246](#)) includes features to negotiate selection of a lossless data compression method as part of the TLS Handshake Protocol and to then apply the algorithm associated with the selected method as part of the TLS Record Protocol. TLS defines one standard compression method, CompressionMethod.null, which specifies that data exchanged via the record protocol will not be compressed. This document describes additional compression methods associated with lossless data compression algorithms for use with TLS.

1. Introduction

The Transport Layer Security (TLS) protocol ([RFC 2246](#), [2]) includes features to negotiate selection of a lossless data compression method as part of the TLS Handshake Protocol and to then apply the algorithm associated with the selected method as part of the TLS Record Protocol. TLS defines one standard compression method, `CompressionMethod.null`, which specifies that data exchanged via the record protocol will not be compressed. While this single compression method helps ensure that TLS implementations are interoperable, the lack of additional standard compression methods has limited the ability of implementers to develop interoperable implementations that include data compression.

TLS is used extensively to secure client-server connections on the World Wide Web. While these connections can often be characterized as short-lived and exchanging relatively small amounts of data, TLS is also being used in environments where connections can be long-lived and the amount of data exchanged can extend into thousands or millions of octets. XML [4], for example, is increasingly being used as a data representation method on the Internet, and XML tends to be verbose. Compression within TLS is one way to help reduce the bandwidth and latency requirements associated with exchanging large amounts of data while preserving the security services provided by TLS.

This document describes additional compression methods associated with lossless data compression algorithms for use with TLS. Standardization of the compressed data formats and compression algorithms associated with the compression methods is beyond the scope of this document.

[2.](#) Compression Methods

TLS [[2](#)] includes the following compression method structure in sections [6.1](#) and [7.4.1.2](#) and Appendix sections A.4.1 and A.6:

```
enum { null(0), (255) } CompressionMethod;
```

which allows for later specification of up to 256 different compression methods. This definition is updated to segregate the range of allowable values into three zones:

1. Values from 0 (zero) through 63 decimal (0x3F) inclusive are reserved for future standardization efforts of the IETF TLS working group.
2. Values from 64 decimal (0x40) through 192 decimal (0xC0) are reserved for assignment by the IANA for specifications developed outside the TLS working group. Assignments from this range of values MUST be made by the IANA and MUST be associated with a formal reference that describes the compression method.
3. Values from 193 decimal (0xC1) through 255 decimal (0xFF) are reserved for private use.

Additional information describing the role of the IANA in the allocation of compression method identifiers is described in [Section 5](#).

In addition, this definition is updated to include assignment of three additional compression methods:

```
enum { null(0), ZLIB(1), LZS(2), RLE(3), (255) } CompressionMethod;
```

The ZLIB compression method is described in [RFC 1950](#) [5]. The Lempel Zif Stac (LZS) compression method is described in ANSI publication X3-241 [6]. The Run Length Encoding (RLE) compression method is described in part 5 of the Digital Imaging and Communications in Medicine standard [7].

[3.](#) Intellectual Property Considerations

Many compression algorithms are subject to patent or other intellectual property rights claims. Implementers are encouraged to seek legal guidance to better understand the implications of developing implementations of the compression methods described in this document.

[4. Internationalization Considerations](#)

The compression method identifiers specified in this document are machine-readable numbers. As such, issues of human internationalization and localization are not introduced.

5. IANA Considerations

This document does not have a direct impact on the IANA, but it does define ranges of compression method values for future assignment. Values from the range reserved for future standardization efforts of the TLS working group MUST be assigned according to the "Standards Action" policy described in [RFC 2434](#) [3]. Values from the range

reserved for private use MUST be used according to the "Private Use" policy described in [RFC 2434](#). Values from the general IANA pool MUST be assigned according to the "IETF Consensus" policy described in [RFC 2434](#).

[6.](#) Security Considerations

This document does not introduce any topics that alter the threat model addressed by TLS. However, data compression prior to encryption can potentially provide a security benefit in "flattening" the distribution of unencrypted octets (or increasing the unicity distance) by using fewer bits to represent common characters. In situations where the unencrypted octets represent human-readable text, reducing the predictability of text patterns can make it slightly more difficult to mount a successful attack on the encrypted octets.

[7.](#) Acknowledgements

The concepts described in this document were originally discussed on the IETF TLS working group mailing list in December, 2000. The author acknowledges the contributions to that discussion provided by Jeffrey Altman, Eric Rescorla, and Marc Van Heyningen.
