Token Binding over HTTP
draft-ietf-tokbind-https-01

Abstract

This document describes a collection of mechanisms that allow HTTP servers to cryptographically bind authentication tokens (such as cookies and OAuth tokens) to a TLS [[RFC5246](#)] connection.

We describe both `_first-party_` as well as `_federated_` scenarios. In a first-party scenario, an HTTP server issues a security token (such as a cookie) to a client, and expects the client to send the security token back to the server at a later time in order to authenticate. Binding the token to the TLS connection between client and server protects the security token from theft, and ensures that the security token can only be used by the client that it was issued to.

Federated token bindings, on the other hand, allow servers to cryptographically bind security tokens to a TLS [[RFC5246](#)] connection that the client has with a `_different_` server than the one issuing the token.

This Internet-Draft is a companion document to The Token Binding Protocol [[TBPROTO](#)]

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on January 1, 2016.

1. Introduction

The Token Binding Protocol [[TBPROTO](#)] defines a Token Binding ID for a TLS connection between a client and a server. The Token Binding ID of a TLS connection is related to a private key that the client proves possession of to the server, and is long-lived (i.e., subsequent TLS connections between the same client and server have the same Token Binding ID). When issuing a security token (e.g. an HTTP cookie or an OAuth token) to a client, the server can include the Token Binding ID in the token, thus cryptographically binding the token to TLS connections between that particular client and server, and inoculating the token against theft by attackers.

While the Token Binding Protocol [[TBPROTO](#)] defines a message format for establishing a Token Binding ID, it doesn't specify how this message is embedded in higher-level protocols. The purpose of this specification is to define how TokenBindingMessages are embedded in HTTP (both versions 1.1 [[RFC2616](#)] and 2 [[I-D.ietf-httpbis-http2](#)]). Note that TokenBindingMessages are only defined if the underlying transport uses TLS. This means that Token Binding over HTTP is only defined when the HTTP protocol is layered on top of TLS (commonly referred to as HTTPS).

HTTP clients establish a Token Binding ID with a server by including a special HTTP header in HTTP requests. The HTTP header value is a TokenBindingMessage.

TokenBindingMessages allow clients to establish multiple Token Binding IDs with the server, by including multiple TokenBinding structures in the TokenBindingMessage. By default, a client will establish a `_provided_` Token Binding ID with the server, indicating a Token Binding ID that the client will persistently use with the server. Under certain conditions, the client can also include a `_referred_` Token Binding ID in the TokenBindingMessage, indicating a Token Binding ID that the client is using with a `_different_` server than the one that the TokenBindingMessage is sent to. This is useful in federation scenarios.

[1.1.](#) Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [[RFC2119](#)].

[2.](#) The Sec-Token-Binding Header

Once a client and server have negotiated the Token Binding Protocol with HTTP/1.1 or HTTP/2 (see The Token Binding Protocol [[TBPROTO](#)]), clients MUST include the Sec-Token-Binding header in their HTTP requests. The ABNF of the Sec-Token-Binding header is:

```
Sec-Token-Binding = "Sec-Token-Binding" ":" [CFWS] EncodedTokenBindingMessage
```

The EncodedTokenBindingMessage is a web-safe Base64-encoding of the TokenBindingMessage as defined in the TokenBindingProtocol [[TBPROTO](#)].

The TokenBindingMessage MUST contain a TokenBinding with TokenBindingType `provided_token_binding`, which MUST be signed with the Token Binding key used by the client for connections between itself and the server that the HTTP request is sent to (clients use

different Token Binding keys for different servers). The Token Binding ID established by this TokenBinding is called a `_Provided Token Binding ID_`

In HTTP/2, the client SHOULD use Header Compression [[I-D.ietf-httpbis-header-compression](#)] to avoid the overhead of repeating the same header in subsequent HTTP requests.

3. Federation Use Cases

3.1. Introduction

For privacy reasons, clients use different private keys to establish Provided Token Binding IDs with different servers. As a result, a server cannot bind a security token (such as an OAuth token or an OpenID Connect identity token) to a TLS connection that the client has with a different server. This is, however, a common requirement in federation scenarios: For example, an Identity Provider may wish to issue an identity token to a client and cryptographically bind that token to the TLS connection between the client and a Relying Party.

In this section we describe mechanisms to achieve this. The common idea among these mechanisms is that a server (called the `_Token Consumer_` in this document) gives the client permission to reveal the Provided Token Binding ID that is used between the client and itself, to another server (called the `_Token Provider_` in this document). Also common across the mechanisms is how the Token Binding ID is revealed to the Token Provider: The client uses the Token Binding Protocol [[TBPROTO](#)], and includes a TokenBinding structure in the `Sec-Token-Binding` HTTP header defined above. What differs between the various mechanisms is `_how_` the Token Consumer grants the permission to reveal the Token Binding ID to the Token Provider. Below we specify one such mechanism, which is suitable for redirect-based interactions between Token Consumers and Token Providers.

3.2. Overview

In a Federated Sign-On protocol, an Identity Provider issues an identity token to a client, which sends the identity token to a Relying Party to authenticate itself. Examples of this include OpenID Connect (where the identity token is called "ID Token") and SAML (where the identity token is a SAML assertion).

To better protect the security of the identity token, the Identity Provider may wish to bind the identity token to the TLS connection between the client and the Relying Party, thus ensuring that only said client can use the identity token: The Relying Party will

compare the Token Binding ID in the identity token with the Token Binding ID of the TLS connection between it and the client.

This is an example of a federation scenario, which more generally can be described as follows:

- o A Token Consumer causes the client to issue a token request to the Token Provider. The goal is for the client to obtain a token and then use it with the Token Consumer.
- o The client delivers the token request to the Token Provider.
- o The Token Provider issues the token. The token is issued for the specific Token Consumer who requested it (thus preventing malicious Token Consumers from using tokens with other Token Consumers). The token is, however, typically a bearer token, meaning that any client can use it with the Token Consumer, not just the client to which it was issued.
- o Therefore, in the previous step, the Token Provider may want to include in the token the Token-Binding public key that the client uses when communicating with the Token Consumer, thus `_binding_` the token to client's Token-Binding keypair. The client proves possession of the private key when communicating with the Token Consumer through the Token Binding Protocol [[TBPROTO](#)], and reveals the corresponding public key of this keypair as part of the Token Binding ID. Comparing the public key from the token with the public key from the Token Binding ID allows the Token Consumer to verify that the token was sent to it by the legitimate client.
- o To allow the Token Provider to include the Token-Binding public key in the token, the Token Binding ID (between client and Token Consumer) must therefore be communicated to the Token Provider along with the token request. Communicating a Token Binding ID involves proving possession of a private key and is described in the Token Binding Protocol [[TBPROTO](#)].

The client will perform this last operation (proving possession of a private key that corresponds to a Token Binding ID between the client and the Token Consumer while delivering the token request to the Token Provider) only if the Token Consumer permits the client to do so.

Below, we specify how Token Consumers can grant this permission during redirect-based federation protocols.

3.3. HTTP Redirects

When a Token Consumer redirects the client to a Token Provider as a means to deliver the token request, it SHOULD include a Include-Referer-Token-Binding-ID HTTP response header in its HTTP response. The ABNF of the Include-Referer-Token-Binding-ID header is:

```
Include-Referer-Token-Binding-ID = "Include-Referer-Token-Binding-ID" ":"  
                                [CFWS] %x74.72.75.65 ; "true", case-  
sensitive
```

Including this response header signals to the client that it should reveal the Token Binding ID used between the client and the Token Consumer to the Token Provider. In the absence of this response header, the client will not disclose any information about the Token Binding used between the client and the Token Consumer to the Token Provider.

This header has only meaning if the HTTP status code is 302 or 301, and MUST be ignored by the client for any other status codes. If the client supports the Token Binding Protocol, and has negotiated the Token Binding Protocol with both the Token Consumer and the Token Provider, it already sends the following header to the Token Provider with each HTTP request (see above):

```
Sec-Token-Binding: EncodedTokenBindingMessage
```

The TokenBindingMessage SHOULD contain a TokenBinding with TokenBindingType referred_token_binding. If included, this TokenBinding MUST be signed with the Token Binding key used by the client for connections between itself and the Token Consumer (more specifically, the web origin that issued the Include-Referer-Token-Binding-ID response header). The Token Binding ID established by this TokenBinding is called a `_Referred Token Binding ID_`.

As described above, the TokenBindingMessage MUST additionally contain a Provided Token Binding ID, i.e., a TokenBinding structure with TokenBindingType provided_token_binding, which MUST be signed with the Token Binding key used by the client for connections between itself and the Token Provider (more specifically, the web origin that the token request sent to).

3.4. Negotiated Key Parameters

The Token Binding Protocol [[TBPROTO](#)] allows the server and client to negotiate a signature algorithm used in the TokenBindingMessage. It is possible that the Token Binding ID used between the client and the

Token Consumer, and the Token Binding ID used between the client and Token Provider, use different signature algorithms. The client MUST use the signature algorithm negotiated with the Token Consumer in the `referred_token_binding` `TokenBinding` of the `TokenBindingMessage`, even if that signature algorithm is different from the one negotiated with the origin that the header is sent to.

Token Providers SHOULD support all the `SignatureAndHashAlgorithms` specified in the Token Binding Protocol [TBPROTO]. If a token provider does not support the `SignatureAndHashAlgorithm` specified in the `referred_token_binding` `TokenBinding` in the `TokenBindingMessage`, it MUST issue an unbound token.

4. Security Considerations

4.1. Security Token Replay

The goal of the Federated Token Binding mechanisms is to prevent attackers from exporting and replaying tokens used in protocols between the client and Token Consumer, thereby impersonating legitimate users and gaining access to protected resources. Bound tokens can still be replayed by malware present in the client. In order to export the token to another machine and successfully replay it, the attacker also needs to export the corresponding private key. The Token Binding private key is therefore a high-value asset and MUST be strongly protected, ideally by generating it in a hardware security module that prevents key export.

4.2. Privacy Considerations

The Token Binding protocol uses persistent, long-lived TLS Token Binding IDs. To protect privacy, TLS Token Binding IDs are never transmitted in clear text and can be reset by the user at any time, e.g. when clearing browser cookies. Unique Token Binding IDs MUST be generated for connections to different origins, so they cannot be used by cooperating servers to link user identities.

4.3. Triple Handshake Vulnerability in TLS

The Token Binding protocol relies on the `tls_unique` value to associate a TLS connection with a TLS Token Binding. The triple handshake attack [TRIPLE-HS] is a known TLS protocol vulnerability allowing the attacker to synchronize `tls_unique` values between TLS connections. The attacker can then successfully replay bound tokens. For this reason, the Token Binding protocol MUST NOT be negotiated unless the Extended Master Secret TLS extension [I-D.ietf-tls-session-hash] has also been negotiated.
