TRILL: ARP/ND Optimization
draft-ietf-trill-arp-optimization-06

Abstract

This document describes mechanisms to optimize the ARP (Address Resolution Protocol) and ND (Neighbor Discovery) traffic in TRILL campus. Such optimization reduces packet flooding over a TRILL campus.

Status of this Memo

This Internet-Draft is submitted to IETF in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF), its areas, and its working groups. Note that other groups may also distribute working documents as Internet-Drafts.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

The list of current Internet-Drafts can be accessed at <http://www.ietf.org/1id-abstracts.html>

The list of Internet-Draft Shadow Directories can be accessed at <http://www.ietf.org/shadow.html>

1 Introduction

ARP [[RFC826](#)] and ND [[RFC4861](#)] are normally sent by broadcast and multicast respectively. To reduce the burden on a TRILL campus caused by these multi-destination messages, RBridges MAY implement an "optimized ARP/ND response", as specified herein, when the target's location is known by the ingress RBridge or can be obtained from a directory. This avoids ARP/ND query flooding.

1.1 Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [[RFC2119](#)].

The acronyms and terminology in [[RFC6325](#)] are used herein. Some of these are listed below for convenience along with some additions:

APPsub-TLV	Application sub-Type-Length-Values
ARP	Address Resolution Protocol [RFC826]
Campus	A TRILL network consisting of RBridges, links, and possibly bridges bounded by end stations and IP routers.
DAD	Duplicate Address Detection
Data Label	VLAN or FGL
ESADI	End Station Address Distribution Information [RFC7357]
FGL	Fine-Grained Label [RFC7172]
IA	Interface Addresses, a TRILL APPsub-TLV [IA-draft]
IP	Internet Protocol
MAC	Media Access Control
ND	Neighbor Discovery [RFC4861]
RBridge	A contraction of "Routing Bridge". A device implementing the TRILL protocol.
SEND	secure neighbor discovery [RFC3971]

TRILL Transparent Interconnection of Lots of Links or
Tunneled Routing in the Link Layer.

2 IP/MAC Address Mappings

By default, an RBridge [[RFC6325](#)] [[RFC7172](#)] learns MAC Address and Data Label (VLAN or FGL) to egress nickname mapping information from TRILL data frames it receives. No IP address information is learned directly from the TRILL data frame. Interface Addresses (IA) APPsub-TLV [[IA-draft](#)] enhances the TRILL base protocol by allowing IP and MAC address mappings to be distributed in the control plane by any RBridge. This APPsub-TLV appears inside the TRILL GENINFO TLV in ESADI [[RFC7357](#)] but the value data structure it specifies may also occur in other application contexts. Edge Directory Assist Mechanisms [[DirMech](#)] makes use of this APPsub-TLV for its push model and uses the value data structure it specifies in its pull model.

An RBridge can easily know the IP/MAC address mappings of the local end stations that it is attached to it via its access ports by receiving ARP [[RFC826](#)] or ND [[RFC4861](#)] messages. If the RBridge has extracted the sender's IP/MAC address pair from the received data packet (either ARP or ND), it MAY save the information and use the IA APPsub-TLV to distribute it to other RBridges through ESADI. Then the relevant remote RBridges (normally those interested in the same Data Label as the original ARP/ND messages) also receive and save such mapping information. There are others ways that RBridges save IP/MAC address mappings in advance, e.g. import from management system and distribution by directory servers [[DirMech](#)].

The examples given above show that RBridges might have saved an end station's triplet of {IP address, MAC address, ingress nickname} for a given Data Label (VLAN or FGL) before that end station sends or receives any real data packet. Note such information might or might not be a complete list and might or might not exist on all RBridges. The information could possibly be from different sources. RBridges can then use the Flags Field in IA APPsub-TLV to identify if the source is a directory server or local observation by the sender. A different confidence level MAY also be used to indicate the reliability of the mapping information.

3 Handling ARP/ND Messages

A native frame that is an ARP [[RFC826](#)] message is detected by its Ethertype of 0x0806. A native frame that is an ND [[RFC4861](#)] is detected by being one of five different ICMPv6 packet types. ARP/ND is commonly used on a link to (1) query for the MAC address

corresponding to an IPv4 or IPv6 address, (2) test if an IPv4/IPv6 address is already in use, or (3) to announce the new or updated info on any of IPv4/IPv6 address, MAC address, and/or point of attachment.

To simplify the text, we use the following terms in this section.

- 1) IP address - indicated protocol address that is normally an IPv4 address in ARP or an IPv6 address in ND.
- 2) sender's IP/MAC address - sender IP/MAC address in ARP, source IP address and source link-layer address in ND
- 3) target's IP/MAC address - target IP/MAC address in ARP, target address and target link-layer address in ND

When an ingress RBridge receives an ARP/ND message, it can perform the steps described in the sub-sections below.

3.1 Get Sender's IP/MAC Mapping Information for Non-zero IP

- o If the sender's IP has not been saved by the ingress RBridge before, populate the information of sender's IP/MAC in its ARP/ND table;
- o else if the sender's IP has been saved before but with a different MAC address mapped or a different ingress nickname associated with the same pair of IP/MAC, the RBridge SHOULD verify if a duplicate IP address has already been in use or an end station has changed its attaching RBridge. The RBridge MAY use different strategies to do so. For example, the RBridge might ask an authoritative entity like directory servers or it might encapsulate and unicast the ARP/ND message to the location where it believes the address is in use. RBridge SHOULD update the saved triplet of {IP address, MAC address, ingress nickname} based on the verification.

The ingress RBridge MAY use the IA APPsub-TLV [[IA-draft](#)] with the Local flag set in ESADI [[RFC7357](#)] to distribute any new or updated triplet of {IP address, MAC address, ingress nickname} information obtained in this step. If a push directory server is used, such information can be distributed as per [[DirMech](#)].

3.2 Determine How to Reply to ARP/ND

- a) If the message is a generic ARP/ND request and the ingress RBridge knows the target's IP address, the ingress RBridge MAY take one or a combination of the following actions:

- a.1. Send an ARP/ND response directly to the querier, with the target's MAC address, as known by the ingress RBridge.
 - a.2. Encapsulate the ARP/ND request to the target's Designated RBridge, and have the egress RBridge for the target forward the query to the target. This behavior has the advantage that a response to the request is authoritative. If the request does not reach the target, then the querier does not get a response.
 - a.3. Block ARP/ND requests that occur for some time after a request to the same target has been launched, and then respond to the querier when the response to the recently-launched query to that target is received.
 - a.4. Pull the most up-to-date records if a pull directory server is available [[DirMech](#)] and reply to the querier.
 - a.5. Flood the request as per [[RFC6325](#)].
- b) If the message is a generic ARP request and the ingress RBridge does not know target's IP address, the ingress RBridge MAY take one of the following actions.
- b.1. Flood the message as per [[RFC6325](#)].
 - b.2. Use directory server to pull the information [[DirMech](#)] and reply to the querier.
 - b.3. Drop the message.
- c) If the message is a gratuitous ARP which can be identified by the same sender's and target's "protocol" address fields or an Unsolicited Neighbor Advertisements [[RFC4861](#)] in ND:

The RBridge MAY use an IA APPsub-TLV [[IA-draft](#)] with the Local flag set to distribute the sender's MAC and IP mapping information. When one or more directory servers are deployed and complete Push Directory information is used by all the RBridges in the Data Label, a gratuitous ARP or unsolicited NA SHOULD be discarded rather than ingressed. Otherwise, they are either ingressed and flooded as per [[RFC6325](#)] or discarded depending on local policy.

- d) If the message is a Address Probe ARP Query [[RFC5227](#)] which can be identified by the sender's protocol (IPv4) address field being zero and the target's protocol address field being the IPv4 address to be tested or a Neighbor Solicitation for DAD (Duplicate Address Detection) which has the unspecified source address [[RFC4862](#)]: it

SHOULD be handled as the generic ARP message as in a) and b).

Note that in the case of secure neighbor discovery (SEND) [[RFC3971](#)], cryptography would prevent local reply by the ingress RBridge, since the RBridge would not be able to sign the response with the target's private key.

It is not essential that all RBridges use the same strategy for which option to select for a particular ARP/ND query. It is up to the implementation.

3.3 Determine How to Handle the ARP/ND Response

If the ingress RBridge R1 decides to unicast the ARP/ND request to the target's egress RBridge R2 as discussed in sub[section 3.2](#) item a) or to flood the request as per [[RFC6325](#)], then R2 decapsulates the query, and initiates an ARP/ND query on the target's link. When/if the target responds, R2 encapsulates and unicasts the response to R1, which decapsulates the response and sends it to the querier. R2 SHOULD initiate a link state update to inform all the other RBridges of the target's location, layer 3 address, and layer 2 address, in addition to forwarding the reply to the querier. The update message can be carried by an IA APPsub-TLV [[IA-draft](#)] with the Local flag set in ESADI [[RFC7357](#)] or as per [[DirMech](#)] if push directory server is in use.

4 Handling RARP (Reverse Address Resolution Protocol) Messages

RARP [[RFC903](#)] uses the same packet format as ARP but a different Ethertype (0x8035) and opcode values. Its use is similar to the generic ARP Request/Response as described in 3.2 a) and b). The difference is that it is intended to query for the target "protocol" (IP) address corresponding to the target "hardware" (MAC) address provided. It SHOULD be handled by doing a local cache or directory server lookup on the target "hardware" address provided to find a mapping to the desired "protocol" address. Normally, it is used to look up a MAC address to find the corresponding IP address.

5 Security Considerations

ARP and ND messages can be easily forged. Therefore the learning of MAC/IP addresses from them should not be considered as reliable. RBridge can use the confidence level in IA APPsub-TLV information received via ESADI or pull directory retrievals to determine the reliability of MAC/IP address mapping. ESADI information can be secured as provide in [[RFC7357](#)] and pull directory information can be secured as provide in [[DirMech](#)]. The implementation decides if an

RBridge will distribute the IP and MAC address mappings received from local native ARP/ND messages to other RBridges in the same Data Label.

The ingress RBridge SHOULD also rate limit the ARP/ND queries for the same target to be injected into the TRILL campus to prevent possible denial of service attacks.

6 IANA Considerations

No IANA action is required. RFC Editor: please delete this section before publication.

7 Acknowledgments

The authors would like to thank Igor Gashinsky for his contributions.
