Using Conditional Router Advertisements for Enterprise Multihoming draft-ietf-v6ops-conditional-ras-04

Abstract

This document discusses the most common scenarios of connecting an enterprise network to multiple ISPs using an address space assigned by an ISP. The problem of enterprise multihoming without address translation of any form has not been solved yet as it requires both the network to select the correct egress ISP based on the packet source address and hosts to select the correct source address based on the desired egress ISP for that traffic. The "ietf-rtgwg-enterprise-pa-multihoming" document proposes a solution to this problem by introducing a new routing functionality (Source Address Dependent Routing) to solve the uplink selection issue and using Router Advertisements to influence the host source address selection. While the above-mentioned document focuses on solving the general problem and on covering various complex use cases, this document describes how the solution proposed in the "ietf-rtgwg-enterprise-pa-multihoming" draft can be adopted for a limited number of common use cases. In particular, the focus is on scenarios where an enterprise network has two Internet uplinks used either in primary/backup mode or simultaneously and hosts in that network might not yet properly support multihoming as described in [RFC8028](#).

1. Introduction

Multihoming is an obvious requirement for many enterprise networks to ensure the desired level of network reliability. However, using more than one ISP (and address space assigned by those ISPs) introduces the problem of assigning IP addresses to hosts. In IPv4 there is no choice but using [\[RFC1918\]](#) address space and NAT ([\[RFC3022\]](#)) at the network edge. Using Provider Independent (PI) address space is not always an option, since it requires running BGP between the enterprise network and the ISPs. Administrative overhead of obtaining and managing PI address space can also be a concern. As IPv6 hosts can, by design, have multiple addresses of the global scope, multihoming using provider address looks even easier for IPv6: each ISP assigns an IPv6 block (usually /48) and hosts in the enterprise network have addresses assigned from each ISP block. However using IPv6 PA blocks in multihoming scenario introduces some challenges, including but not limited to:

- o Selecting the correct uplink based on the packet source address;
- o Signaling to hosts that some source addresses should or should not be used (e.g. an uplink to the ISP went down or became available again).

The document [\[I-D.ietf-rtgwg-enterprise-pa-multihoming\]](#) discusses these and other related challenges in detail in relation to the general multihoming scenario for enterprise networks and proposes solution which relies heavily on the rule 5.5 of the default address selection algorithm ([\[RFC6724\]](#)). The rule 5.5 makes hosts prefer source addresses in a prefix advertised by the next-hop and therefore is very useful in multihomed scenarios when different routers may advertise different prefixes. Unfortunately that rule has not been widely implemented when this document was written. Therefore network administrators in enterprise networks can't yet assume that all devices in their network support the rule 5.5, especially in the quite common BYOD ("Bring Your Own Device") scenario. However, while it does not seem feasible to solve all the possible multihoming scenarios without relying on rule 5.5, it is possible to provide IPv6 multihoming using provider-assigned (PA) address space for the most common use cases. This document discusses how the general solution described in [\[I-D.ietf-rtgwg-enterprise-pa-multihoming\]](#) can be applied to scenarios when:

- o An enterprise network has two or more ISP uplinks;
- o Those uplinks are used for Internet access in active/backup or load sharing mode w/o any sophisticated traffic engineering requirements;

- o Each ISP assigns the network a subnet from its own PA address space
- o Hosts in the enterprise network are not expected to support the Rule 5.5 of the default address selection algorithm ([\[RFC6724\]](#)).

2. Common Enterprise Multihoming Scenarios

2.1. Two ISP Uplinks, Primary and Backup

This scenario has the following key characteristics:

- o The enterprise network is using uplinks to two (or more) ISPs for Internet access;
- o Each ISP assigns IPv6 PA address space for the network;
- o Uplink(s) to one ISP is a primary (preferred) one. All other uplinks are backup and are not expected to be used while the primary one is operational;
- o If the primary uplink is operational, all Internet traffic should flow via that uplink;
- o When the primary uplink fails the Internet traffic needs to flow via the backup uplinks;
- o Recovery of the primary uplink needs to trigger the traffic switchover from the backup uplinks back to primary one;
- o Hosts in the enterprise network are not expected to support the Rule 5.5 of the default address selection algorithm ([\[RFC6724\]](#)).

2.2. Two ISP Uplinks, Used for Load Balancing

This scenario has the following key characteristics:

- o The enterprise network is using uplinks to two (or more) ISPs for Internet access;
- o Each ISP assigns an IPv6 PA address space;
- o All the uplinks may be used simultaneously, with the traffic flows being randomly (not necessarily equally) distributed between them;
- o Hosts in the enterprise network are not expected to support the Rule 5.5 of the default address selection algorithm ([\[RFC6724\]](#)).

3. Conditional Router Advertisements

3.1. Solution Overview

3.1.1. Uplink Selection

As discussed in [[I-D.ietf-rtgwg-enterprise-pa-multihoming](#)], one of the two main problems to be solved in the enterprise multihoming scenario is the problem of the next-hop (uplink) selection based on the packet source address. For example, if the enterprise network has two uplinks, to ISP_A and ISP_B, and hosts have addresses from subnet_A and subnet_B (belonging to ISP_A and ISP_B respectively) then packets sourced from subnet_A must be sent to ISP_A uplink while packets sourced from subnet_B must be sent to ISP_B uplink.

While some work is being done in the Source Address Dependent Routing (SADR) area, the simplest way to implement the desired functionality currently is to apply a policy which selects a next-hop or an egress interface based on the packet source address. Most SMB/Enterprise grade routers have such functionality available currently.

3.1.2. Source Address Selection and Conditional RAs

Another problem to be solved in the multihoming scenario is the source address selection on hosts. In the normal situation (all uplinks are up/operational) hosts have multiple global unique addresses and can rely on the default address selection algorithm ([[RFC6724](#)]) to pick up a source address, while the network is responsible for choosing the correct uplink based on the source address selected by a host as described in [Section 3.1.2](#). However, some network topology changes (i.e. changing uplink status) might affect the global reachability for packets sourced from the particular prefixes and therefore such changes have to be signaled back to the hosts. For example:

- o An uplink to an ISP_A went down. Hosts should not use addresses from ISP_A prefix;
- o A primary uplink to ISP_A which was not operational has come back up. Hosts should start using the source addresses from ISP_A prefix.

[[I-D.ietf-rtgwg-enterprise-pa-multihoming](#)] provides a detailed explanation on why SLAAC and router advertisements are the most suitable mechanism for signaling network topology changes to hosts and thereby influencing the source address selection. Sending a router advertisement to change the preferred lifetime for a given prefix provides the following functionality:

- o deprecating addresses (by sending an RA with the preferred_lifetime set to 0 in the corresponding PIO (Prefix Information option, [[RFC4861](#)])) to indicate to hosts that that addresses from that prefix should not be used;
- o making a previously unused (deprecated) prefix usable again (by sending an RA containing a POI with non-zero preferred lifetime) to indicate to hosts that addresses from that prefix can be used again.

To provide the desired functionality, first-hop routers are required to

- o send RA triggered by defined event policies in response to uplink status change event; and
- o while sending periodic or solicited RAs, set the value in the given RA field (e.g. PIO preferred lifetime) based on the uplink status.

The exact definition of the 'uplink status' depends on the network topology and may include conditions like:

- o uplink interface status change;
 - o presence of a particular route in the routing table;
 - o presence of a particular route with a particular attribute (next-hop, tag etc) in the routing table;
 - o protocol adjacency change.
- etc.

In some scenarios, when two routers are providing first-hop redundancy via VRRP, the master-backup status can be considered as a condition for sending RAs and changing the preferred lifetime value. See [Section 3.2.2](#) for more details.

If hosts are provided with ISP DNS servers IPv6 addresses via RDNSS [[RFC8106](#)] it might be desirable for the conditional RAs to update the Lifetime field of the RDNSS option as well.

The trigger is not only forcing the router to send an unsolicited RA to propagate the topology changes to all hosts. Obviously the RA fields values (like PIO Preferred Lifetime or DNS Server Lifetime) changed by the particular trigger need to stay the same until another event happens causing the value to be updated. E.g. if the ISP_A

uplink failure causes the prefix to be deprecated, all solicited and unsolicited RAs sent by the router need to have the Preferred Lifetime for that POI set to 0 until the uplink comes back up.

It should be noted that the proposed solution is quite similar to the existing requirement L-13 for IPv6 CPE routers ([RFC7084]) and the documented behavior of homenet devices. It is using the same mechanism of deprecating a prefix when the corresponding uplink is not operational, applying it to enterprise network scenario.

3.2. Example Scenarios

This section illustrates how the conditional RAs solution can be applied to most common enterprise multihoming scenarios, described in [Section 2](#).

3.2.1. Single Router, Primary/Backup Uplinks

Figure 1: Single Router, Primary/Backup Uplinks

Let's look at a simple network topology where a single router acts as a border router to terminate two ISP uplinks and as a first-hop router for hosts. Each ISP assigns a /48 to the network, and the ISP_A uplink is a primary one, to be used for all Internet traffic, while the ISP_B uplink is a backup, to be used only when the primary uplink is not operational.

To ensure that packets with source addresses from ISP_A and ISP_B are only routed to ISP_A and ISP_B uplinks respectively, the network administrator needs to configure a policy on R1:

```
IF (packet_source_address is in 2001:db8:1::/48) and
(packet_destination_address is not in (2001:db8:1::/48 or 2001:db8:2::/48))
    THEN
```

```
        default next-hop is ISP_A_uplink
```

```
IF (packet_source_address is in 2001:db8:2::/48) and
(packet_destination_address is not in (2001:db8:1::/48 or 2001:db8:2::/48))
    THEN
```

```
        default next-hop is ISP_B_uplink
```

Under normal circumstances it is desirable that all traffic be sent via the ISP_A uplink, therefore hosts (the host H1 in the example topology figure) should be using source addresses from 2001:db8:1:1::/64. When/if ISP_A uplink fails, hosts should stop using the 2001:db8:1:1::/64 prefix and start using 2001:db8:2:1::/64 until the ISP_A uplink comes back up. To achieve this the router advertisement configuration on the R1 device for the interface facing H1 needs to have the following policy:

```
prefix 2001:db8:1:1::/64 {
    IF (ISP_A_uplink is up)
        THEN
            preferred_lifetime = 604800
        ELSE
            preferred_lifetime = 0
}
```

```
prefix 2001:db8:2:1::/64 {
    IF (ISP_A_Uplink is up)
        THEN
            preferred_lifetime = 0
        ELSE
            preferred_lifetime = 604800
}
```

A similar policy needs to be applied to the RDNSS Lifetime if ISP_A and ISP_B DNS servers are used.

3.2.2. Two Routers, Primary/Backup Uplinks

Let's look at a more complex scenario where two border routers are terminating two ISP uplinks (one each), acting as redundant first-hop routers for hosts. The topology is shown on Fig.2

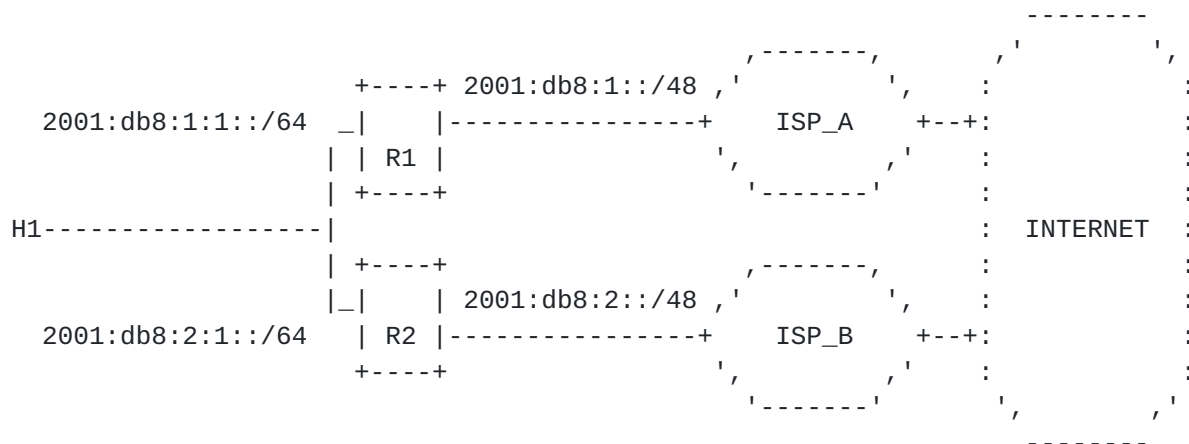

Figure 2: Two Routers, Primary/Backup Uplinks

In this scenario R1 sends RAs with PIO for 2001:db8:1:1::/64 (ISP_A address space) and R2 sends RAs with PIO for 2001:db8:2:1::/64 (ISP_B address space). Each router needs to have a forwarding policy configured for packets received on its hosts-facing interface:

```

IF (packet_source_address is in 2001:db8:1::/48) and
(packet_destination_address is not in (2001:db8:1::/48 or 2001:db8:2::/48))
  THEN
    default next-hop is ISP_A_uplink

IF (packet_source_address is in 2001:db8:2::/48) and
(packet_destination_address is not in (2001:db8:1::/48 or 2001:db8:2::/48))
  THEN
    default next-hop is ISP_B_uplink
  
```

In this case there is more than one way to ensure that hosts are selecting the correct source address based on the uplink status. If VRRP is used to provide first-hop redundancy and the master router is the one with the active uplink, then the simplest way is to use the VRRP mastership as a condition for router advertisement. So, if ISP_A is the primary uplink, the routers R1 and R2 need to be configured in the following way:

R1 is the VRRP master by default (when ISP_A uplink is up). If ISP_A uplink is down, then R1 becomes a backup. Router advertisements on R1's interface facing H1 needs to have the following policy applied:

```
prefix 2001:db8:1:1::/64 {  
    IF (vrrp_master)  
        THEN  
            preferred_lifetime = 604800  
        ELSE  
            preferred_lifetime = 0  
    }  
}
```

R2 is VRRP backup by default. Router advertisement on R2 interface facing H1 needs to have the following policy applied:

```
prefix 2001:db8:2:1::/64 {  
    IF(vrrp_master)  
        THEN  
            preferred_lifetime = 604800  
        ELSE  
            preferred_lifetime = 0  
    }  
}
```

If VRRP is not used or interface status tracking is not used for mastership switchover, then each router needs to be able to detect the uplink failure/recovery on the neighboring router, so that RAs with updated preferred lifetime values are triggered. Depending on the network setup various triggers like a route to the uplink interface subnet or a default route received from the uplink can be used. The obvious drawback of using the routing table to trigger the conditional RAs is that some additional configuration is required. For example, if a route to the prefix assigned to the ISP uplink is used as a trigger, then the conditional RA policy would have the following logic:

R1:

```
prefix 2001:db8:1:1::/64 {  
    IF (ISP_A_uplink is up)  
        THEN  
            preferred_lifetime = 604800  
        ELSE  
            preferred_lifetime = 0  
    }  
}
```

R2:

```
prefix 2001:db8:2:1::/64 {
    IF (ISP_A_uplink_route is present)
        THEN
            preferred_lifetime = 0
        ELSE
            preferred_lifetime = 604800
}
```

3.2.3. Single Router, Load Balancing Between Uplinks

Let's look at the example topology shown in Figure 1, but with both uplinks used simultaneously. In this case R1 would send RAs containing PIOs for both prefixes, 2001:db8:1:1::/64 and 2001:db8:2:1::/64, changing the preferred lifetime based on particular uplink availability. If the interface status is used as uplink availability indicator, then the policy logic would look like the following:

```
prefix 2001:db8:1:1::/64 {
    IF (ISP_A_uplink is up)
        THEN
            preferred_lifetime = 604800
        ELSE
            preferred_lifetime = 0
}
prefix 2001:db8:2:1::/64 {
    IF (ISP_B_uplink is up)
        THEN
            preferred_lifetime = 604800
        ELSE
            preferred_lifetime = 0
}
```

R1 needs a forwarding policy to be applied to forward packets to the correct uplink based on the source address as described in [Section 3.2.1](#).

3.2.4. Two Router, Load Balancing Between Uplinks

In this scenario the example topology is similar to the one shown in Figure 2, but both uplinks can be used at the same time. It means that both R1 and R2 need to have the corresponding forwarding policy to forward packets based on their source addresses.

Each router would send RAs with POI for the corresponding prefix. setting preferred_lifetime to a non-zero value when the ISP uplink is up, and deprecating the prefix by setting the preferred lifetime to 0 in case of uplink failure. The uplink recovery would trigger another

RA with non-zero preferred lifetime to make the addresses from the prefix preferred again. The example RA policy on R1 and R2 would look like:

R1:

```
prefix 2001:db8:1:1::/64 {  
    IF (ISP_A_uplink is up)  
        THEN  
            preferred_lifetime = 604800  
        ELSE  
            preferred_lifetime = 0  
    }  
}
```

R2:

```
prefix 2001:db8:2:1::/64 {  
    IF (ISP_B_uplink is up)  
        THEN  
            preferred_lifetime = 604800  
        ELSE  
            preferred_lifetime = 0  
    }  
}
```

3.2.5. Topologies with Dedicated Border Routers

For simplicity, all topologies below show the ISP uplinks terminated on the first-hop routers. Obviously, the proposed approach can be used in more complex topologies when dedicated devices are used for terminating ISP uplinks. In that case VRRP mastership or interface status can not be used as a trigger for conditional RAs and route presence as described above should be used instead.

Let's look at the example topology shown on the Figure 3:

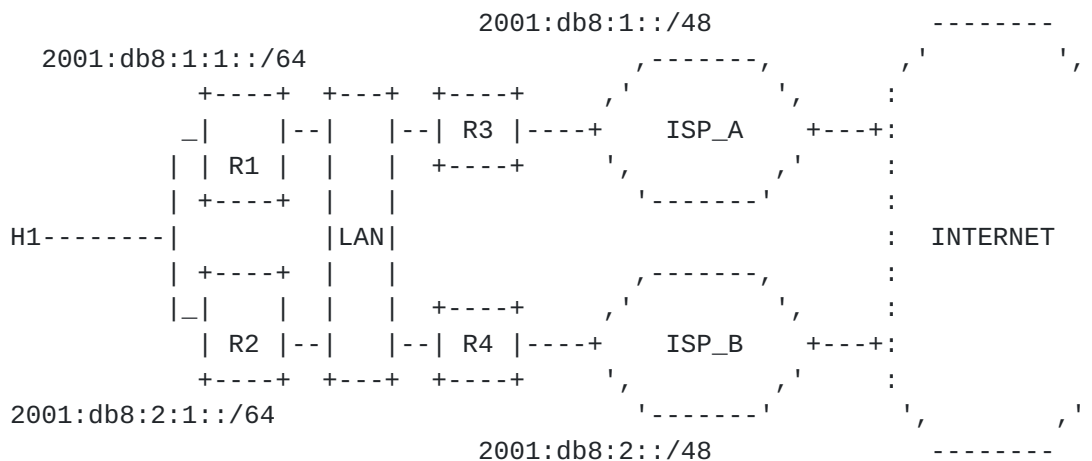

Figure 3: Dedicated Border Routers

For example, if ISP_A is a primary uplink and ISP_B is a backup one then the following policy might be used to achieve the desired behaviour (H1 is using ISP_A address space, 2001:db8:1:1::/64 while ISP_A uplink is up and only using ISP_B 2001:db8:2:1::/64 prefix if the uplink is non-operational):

R1 and R2 policy:

```

prefix 2001:db8:1:1::/64 {
    IF (ISP_A_uplink_route is present)
        THEN
            preferred_lifetime = 604800
        ELSE
            preferred_lifetime = 0
}

prefix 2001:db8:2:1::/64 {
    IF (ISP_A_uplink_route is present)
        THEN
            preferred_lifetime = 0
        ELSE
            preferred_lifetime = 604800
}

```

For the load-balancing case the policy would look slightly different: each prefix has non-zero preferred_lifetime only if the corresponding ISP uplink route is present:

```
prefix 2001:db8:1:1::/64 {  
    IF (ISP_A_uplink_route is present)  
        THEN  
            preferred_lifetime = 604800  
        ELSE  
            preferred_lifetime = 0  
    }  
  
prefix 2001:db8:2:1::/64 {  
    IF (ISP_B_uplink_route is present)  
        THEN  
            preferred_lifetime = 604800  
        ELSE  
            preferred_lifetime = 0  
    }
```

3.2.6. Intra-Site Communication during Simultaneous Uplinks Outage

Prefix deprecation as a result of an uplink status change might lead to a situation when all global prefixes are deprecated (all ISP uplinks are not operational for some reason). Even when there is no Internet connectivity it might be still desirable to have intra-site IPv6 connectivity (especially when the network in question is an IPv6-only one). However while an address is in a deprecated state, its use is discouraged, but not strictly forbidden ([RFC4862]). In such a scenario all IPv6 source addresses in the candidate set ([RFC6724]) are deprecated, which means that they still can be used (as there is no preferred addresses available) and the source address selection algorithm can pick up one of them, allowing the intra-site communication. However some OSes might just fall back to IPv4 if the network interface has no preferred IPv6 global addresses. Therefore if intra-site connectivity is vital during simultaneous outages of multiple uplinks, administrators might consider using ULAs or provisioning additional backup uplinks to protect the network from double-failure cases.

3.2.7. Uplink Damping

If an actively used uplink (primary one or one used in load balancing scenario) starts flapping, it might lead to the undesirable situation of flapping addresses on hosts (every time the uplink goes up hosts receive an RA with non-zero preferred PIO lifetime, and every time the uplink goes down all addresses in the affected prefix become deprecated). This would, undoubtedly, negatively impact the user experience, not to mention the impact of spikes of DAD traffic every time an uplink comes back up. Therefore it's recommended that router vendors implement some form of damping policy for conditional RAs and either postpone sending an RA with non-zero lifetime for a POI when

the uplink comes up for a number of seconds or even introduce accumulated penalties/exponential backoff algorithm for such delays. (In the case of a multiple simultaneous uplink failure scenario, when all but one uplinks are down and the last remaining is flapping it might result in all addresses being deprecated for a while after the flapping uplink recovers.)

3.3. Solution Limitations

It should be noted that the proposed approach is not a silver bullet for all possible multihoming scenarios. It would work very well for networks with relatively simple topologies and straightforward routing policies. The more complex the network topology and the corresponding routing policies, the more configuration would be required to implement the solution.

Another limitation is related to the load balancing between the uplinks. In the scenario in which both uplinks are active, hosts would select the source prefix using the Default Address Selection algorithm ([RFC6724]), and therefore the load between two uplinks most likely would not be evenly distributed. (However, the proposed mechanism does allow a creative way of controlling uplinks load in SDN networks where controllers might selectively deprecate prefixes on some hosts but not others to move egress traffic between uplinks). Also the prefix selection does not take into account any other uplinks properties (such as RTT etc), so egress traffic might not be sent to the nearest uplink if the corresponding prefix is selected as a source. In general, if not all uplinks are equal and some uplinks are expected to be preferred over others, then the network administrator should ensure that prefixes from non-preferred ISP(s) are kept deprecated (so primary/backup setup is used).

3.3.1. Connections Preservation

The proposed solution is not designed to preserve connection state after an uplink failure. If all uplinks to an ISP go down, all sessions to/from addresses from that ISP address space are interrupted as there is no egress path for those packets and there is not return path from the Internet to the corresponding prefix. In this regard it is similar to IPv4 multihoming using NAT, where an uplink failure and failover to another uplink means that a public IPv4 address changes and all existing connections are interrupted.

An uplink recovery, however, does not necessarily lead to connections interruption. In the load sharing/balancing scenario an uplink recovery does not affect any existing connections at all. In the active/backup topology when the primary uplink recovers from the failure and the backup prefix is deprecated, the existing sessions

(established to/from the backup ISP addresses) can be preserved if the routers are configured as described in [Section 3.2.1](#) and send packets with the backup ISP source addresses to the backup uplink even when the primary one is operational. As a result, the primary uplink recovery makes the usage of the backup ISP addresses discouraged but still possible.

It should be noted that in IPv4 multihoming with NAT, when the egress interface is chosen without taking packet source address into account (as internal hosts usually have addresses from [[RFC1918](#)] space), sessions can not be preserved after an uplink recovery.
