Message Encryption for Web Push draft-ietf-webpush-encryption-08

Abstract

A message encryption scheme is described for the Web Push protocol. This scheme provides confidentiality and integrity for messages sent from an Application Server to a User Agent.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at http://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on August 18, 2017.

1. Introduction

The Web Push protocol [I-D.ietf-webpush-protocol] is an intermediated protocol by necessity. Messages from an Application Server are delivered to a User Agent via a Push Service.

This document describes how messages sent using this protocol can be secured against inspection, modification and falsification by a Push Service.

Web Push messages are the payload of an HTTP message [RFC7230]. These messages are encrypted using an encrypted content encoding

[<u>I-D.ietf-httpbis-encryption-encoding</u>]. This document describes how this content encoding is applied and describes a recommended key management scheme.

For efficiency reasons, multiple users of Web Push often share a central agent that aggregates push functionality. This agent can enforce the use of this encryption scheme by applications that use push messaging. An agent that only delivers messages that are properly encrypted strongly encourages the end-to-end protection of messages.

A web browser that implements the Web Push API [API] can enforce the use of encryption by forwarding only those messages that were properly encrypted.

1.1. Notational Conventions

The words "MUST", "MUST NOT", "SHOULD", and "MAY" are used in this document. It's not shouting, when they are capitalized, they have the special meaning described in [RFC2119].

2. Push Message Encryption Overview

Encrypting a push message uses elliptic-curve Diffie-Hellman (ECDH) [ECDH] on the P-256 curve [FIPS186] to establish a shared secret (see Section 3.1) and a symmetric secret for authentication (see Section 3.2).

A User Agent generates an ECDH key pair and authentication secret that it associates with each subscription it creates. The ECDH public key and the authentication secret are sent to the Application Server with other details of the push subscription.

When sending a message, an Application Server generates an ECDH key pair and a random salt. The ECDH public key is encoded into the "dh" parameter of the Crypto-Key header field; the salt is encoded into message payload. The ECDH key pair can be discarded after encrypting the message.

The content of the push message is encrypted or decrypted using a content encryption key and nonce that is derived using all of these inputs and the process described in Section 3.

2.1. Key and Secret Distribution

The application using the subscription distributes the subscription public key and authentication secret to an authorized Application Server. This could be sent along with other subscription information

that is provided by the User Agent, such as the push subscription URI.

An application MUST use an authenticated, confidentiality protected communications medium for this purpose. In addition to the reasons described in [I-D.ietf-webpush-protocol], this ensures that the authentication secret is not revealed to unauthorized entities, which can be used to generate push messages that will be accepted by the User Agent.

Most applications that use push messaging have a pre-existing relationship with an Application Server. Any existing communication mechanism that is authenticated and provides confidentiality and integrity, such as HTTPS [RFC2818], is sufficient.

3. Push Message Encryption

Push message encryption happens in four phases:

- o A shared secret is derived using elliptic-curve Diffie-Hellman [ECDH] (Section 3.1).
- o The shared secret is then combined with the application secret to produce the input keying material used in [I-D.ietf-httpbis-encryption-encoding] (Section 3.3).
- o A content encryption key and nonce are derived using the process in [I-D.ietf-httpbis-encryption-encoding].
- o Encryption or decryption follows according to [I-D.ietf-httpbis-encryption-encoding].

The key derivation process is summarized in $\frac{\text{Section 3.4}}{\text{Section 5}}$. Restrictions on the use of the encrypted content coding are described in $\frac{\text{Section 4}}{\text{Section 4}}$.

3.1. Diffie-Hellman Key Agreement

For each new subscription that the User Agent generates for an Application, it also generates a P-256 [FIPS186] key pair for use in elliptic-curve Diffie-Hellman (ECDH) [ECDH].

When sending a push message, the Application Server also generates a new ECDH key pair on the same P-256 curve.

The ECDH public key for the Application Server is included as the "keyid" parameter in the encrypted content coding header (see Section 2.1 of [I-D.ietf-httpbis-encryption-encoding].

An Application combines its ECDH private key with the public key provided by the User Agent using the process described in [ECDH]; on receipt of the push message, a User Agent combines its private key with the public key provided by the Application Server in the "dh" parameter in the same way. These operations produce the same value for the ECDH shared secret.

3.2. Push Message Authentication

To ensure that push messages are correctly authenticated, a symmetric authentication secret is added to the information generated by a User Agent. The authentication secret is mixed into the key derivation process shown in <u>Section 3.3</u>.

A User Agent MUST generate and provide a hard to guess sequence of 16 octets that is used for authentication of push messages. This SHOULD be generated by a cryptographically strong random number generator [RFC4086].

3.3. Combining Shared and Authentication Secrets

The shared secret produced by ECDH is combined with the authentication secret using HMAC-based key derivation function (HKDF) described in [RFC5869]. This produces the input keying material used by [I-D.ietf-httpbis-encryption-encoding].

The HKDF function uses SHA-256 hash algorithm [FIPS180-4] with the following inputs:

salt: the authentication secret

IKM: the shared secret derived using ECDH

info: the concatenation of the ASCII-encoded string "WebPush: info", a zero octet, the X9.62 encoding of the User Agent ECDH public key, and X9.62 encoding of the Application Server ECDH public key; that is

key_info = "WebPush: info" || 0x00 || ua_public || as_public

L: 32 octets (i.e., the output is the length of the underlying SHA-256 HMAC function output)

3.4. Encryption Summary

This results in a the final content encryption key and nonce generation using the following sequence, which is shown here in

pseudocode with HKDF expanded into separate discrete steps using HMAC with SHA-256:

```
-- For a User Agent:
ecdh_secret = ECDH(ua_private, as_public)
auth_secret = random(16)
-- For an Application Server:
ecdh_secret = ECDH(as_private, ua_public)
auth_secret = <from User Agent>
-- For both:
PRK_key = HMAC-SHA-256(auth_secret, ecdh_secret)
key_info = "WebPush: info" || 0x00 || ua_public || as_public
IKM = HMAC-SHA-256(PRK_cek, key_info || 0x01)
salt = random(16)
PRK = HMAC-SHA-256(salt, IKM)
cek_info = "Content-Encoding: aes128gcm" || 0x00
CEK = HMAC-SHA-256(PRK, cek_info || 0x01)[0..15]
nonce_info = "Content-Encoding: nonce" || 0x00
NONCE = HMAC-SHA-256(PRK, nonce_info || 0x01)[0..11]
```

Note that this omits the exclusive OR of the final nonce with the record sequence number, since push messages contain only a single record (see <u>Section 4</u>) and the sequence number of the first record is zero.

4. Restrictions on Use of "aes128gcm" Content Coding

An Application Server MUST encrypt a push message with a single record. This allows for a minimal receiver implementation that handles a single record. An application server MUST set the "rs" parameter in the "aes128gcm" content coding header to a size that is greater than the some of the length of the plaintext, the padding delimiter (1 octet), any padding, and the authentication tag (16 octets).

A push message MUST include the application server ECDH public key in the "keyid" parameter of the encrypted content coding header. The uncompressed point form defined in $[\underline{\mathsf{X9.62}}]$ (that is, a 65 octet sequence that starts with a 0x04 octet) forms the entirety of the "keyid".

A push service is not required to support more than 4096 octets of payload body (see Section 7.2 of [I-D.ietf-webpush-protocol]). Absent header (86 octets), padding (minimum 2 octets), and expansion

for AEAD_AES_128_GCM (16 octets), this equates to at most 3992 octets of plaintext.

An Application Server MUST NOT use other content encodings for push messages. In particular, content encodings that compress could result in leaking of push message contents. The Content-Encoding header field therefore has exactly one value, which is "aes128gcm". Multiple "aes128gcm" values are not permitted.

A User Agent is not required to support multiple records. A User Agent MAY ignore the "rs" field. If a record size is unchecked, decryption will fail with high probability for all valid cases. The padding delimiter octet MUST be checked, values other than 0x02 MUST cause the message to be discarded.

5. Push Message Encryption Example

The following example shows a push message being sent to a push service.

POST /push/JzLQ3raZJfFBR0aqv0MsLrt54w4rJUsV HTTP/1.1

Host: push.example.net

TTL: 10

Content-Length: 145

Content-Encoding: aes128gcm

DGv6ra1nlYgDCS1FRnbzlwAAEABBBP4z9KsN6nGRTbVYI_c7VJSPQTBtkgcy27ml mlMoZIIgDll6e3vCYLocInmYWAmS6TlzAC8wEqKK6PBru3jl7A_yl95bQpu6cVPT pK4Mqqkf1CXztLVBSt2Ks3oZwbuwXPXLWyouBWLVWGNWQexSqSxsj_Qulcy4a-fN

This example shows the ASCII encoded string, "When I grow up, I want to be a watermelon". The content body is shown here with line wrapping and URL-safe base64url encoding to meet presentation constraints.

The keys used are shown below using the uncompressed form $[\underline{X9.62}]$ encoded using base64url.

Authentication Secret: BTBZMqHH6r4Tts7J_aSIgg Receiver:

Sender:

 $\verb|private| key: yfWPiYE-n46HLnH0KqZ0F1fJJU3MYrct3AELtAQ-oRw| \\$

public key: <the value of the "dh" parameter>

Intermediate values for this example are included in Appendix A.

6. IANA Considerations

[[RFC EDITOR: please remote this section before publication.]] This document makes no request of IANA.

Security Considerations

The security considerations of [I-D.ietf-httpbis-encryption-encoding] describe the limitations of the content encoding. In particular, any HTTP header fields are not protected by the content encoding scheme. A User Agent MUST consider HTTP header fields to have come from the Push Service. An application on the User Agent that uses information from header fields to alter their processing of a push message is exposed to a risk of attack by the Push Service.

The timing and length of communication cannot be hidden from the Push Service. While an outside observer might see individual messages intermixed with each other, the Push Service will see what Application Server is talking to which User Agent, and the subscription that is used. Additionally, the length of messages could be revealed unless the padding provided by the content encoding scheme is used to obscure length.

<u>Appendix A</u>. Intermediate Values for Encryption

The intermediate values calculated for the example in $\underline{\text{Section 5}}$ are shown here. The following are inputs to the calculation:

Plaintext: V2hlbiBJIGdyb3cgdXAsIEkgd2FudCB0byBiZSBhIHdhdGVybWVsb24

Application Server public key (as_public):
BP4z9KsN6nGRTbVYI_c7VJSPQTBtkgcy27mlmlMoZIIg
Dll6e3vCYLocInmYWAmS6TlzAC8wEqKK6PBru3j17A8

```
Application Server private key (as_private): yfWPiYE-n46HLnH0KqZ0F1f JJU3MYrct3AELtAQ-oRw
```

User Agent public key (ua_public): BCVxsr7N_eNgVRqvHtD0zTZsEc6-VV-JvLexhqUzORcx a0zi6-AYWXvTBHm4bjyPjs7Vd8pZGH6SRpkNtoIAiw4

User Agent private key (ua_private):
 q1dXpw3UpT5V0mu_cf_v6ih07Aems3njxI-JWqLcM94

Salt: DGv6ra1nlYgDCS1FRnbzlw

Authentication secret (auth_secret): BTBZMqHH6r4Tts7J_aSIgg

Note that knowledge of just one of the private keys is necessary. The Application Server randomly generates the salt value, whereas salt is input to the receiver.

This produces the following intermediate values:

Shared ECDH secret (ecdh_secret): kyrL1jII0HEzg3sM2ZWRHDRB62YACZhhS1 knJ672kSs

Pseudo-random key for key combining (PRK_key): Snr3JMxaHVDXHWJn5wdC52WjpCtd2EIEGBykDcZW32k

Info for key combining (key_info): V2ViUHVzaDogaW5mbwAEJXGyvs3942BVG

 bZIHMtu5pZpTKGSCIA5Zent7wmC6HCJ5mFgJkuk5cwAv MBKiiujwa7t45ewP

Input keying material for content encryption key derivation (IKM): S4lYMb_L0FxCeq0WhDx813KgSYqU26kOyzWUdsXYyrg

PRK for content encryption (PRK): 09_eUZGrsvxChDCGRCdkLiDXrReG0EVeSC dCcPBSJSc

Info for content encryption key derivation (cek_info):
 Q29udGVudC1FbmNvZGluZzogYWVzMTI4Z2NtAA

Content encryption key (CEK): oIhVW04MRdy2XN9CiKLxTg

Info for content encryption nonce derivation (nonce_info):
 Q29udGVudC1FbmNvZGluZzogbm9uY2UA

Nonce (NONCE): 4h_95klXJ5E_qnoN

The salt, record size of 4096, and application server public key produce an 86 octet header of DGv6ra1nlYgDCS1FRnbzlwAAEABBBP4z

 $9 Ks N6 nGRTbVYI_c7 VJSPQTBtkgcy27 ml mlMoZIIgDll6 e3 vCYLocInmYWAmS6Tlz AC8 wEqKK6PBru3jl7A8. \\$

The push message plaintext has the padding delimiter octet (0x02) appended to produce V2hlbiBJIGdyb3cgdXAsIEkgd2FudCB0 byBiZSBhIHdhdGVybWVsb24C. The plaintext is then encrypted with AES-GCM, which emits ciphertext of 8pfeW0KbunFT06SuDKoJH9Ql87S1QUrd irN6GcG7sFz1y1sqLgVi1VhjVkHsUoEs bI_0LpXMuGvnzQ.

The header and cipher text are concatenated and produce the result shown in $\underbrace{\text{Section 5}}$.
