**The OCB Authenticated-Encryption Algorithm**  
**draft-irtf-cfrg-ocb-07**

**Abstract**

This document specifies OCB, a shared-key blockcipher-based encryption scheme that provides confidentiality and authenticity for plaintexts and authenticity for associated data. This document is a product of the Crypto Forum Research Group (CFRG).

**Status of This Memo**

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on August 10, 2014.

## [1.](#) Introduction

Schemes for authenticated encryption (AE) simultaneously provide for confidentiality and authentication. While this goal would traditionally be achieved by melding separate encryption and authentication mechanisms, each using its own key, integrated AE schemes intertwine what is needed for confidentiality and what is needed for authenticity. By conceptualizing AE as a single cryptographic goal, AE schemes are less likely to be misused than conventional encryption schemes. Also, integrated AE schemes can be significantly faster than what one sees from composing separate confidentiality and authenticity means.

When an AE scheme allows for the authentication of unencrypted data at the same time that a plaintext is being encrypted and authenticated, the scheme is an authenticated encryption with associated data (AEAD) scheme. Associated data can be useful when, for example, a network packet has unencrypted routing information and an encrypted payload.

OCB (short for Offset Codebook) is an AEAD scheme that depends on a blockcipher. This document fully defines OCB encryption and decryption except for the choice of the blockcipher and the length of authentication tag that is part of the ciphertext. The blockcipher must have a 128-bit blocksize. Each choice of blockcipher and tag length specifies a different variant of OCB. Several AES-based variants are defined in [Section 3.1](#).

OCB encryption and decryption employ a nonce  $N$ , which must be distinct for each invocation of the OCB encryption operation. OCB requires the associated data  $A$  to be specified when one encrypts or decrypts, but it may be zero-length. The plaintext  $P$  and the associated data  $A$  can have any bitlength. The ciphertext  $C$  one gets by encrypting  $P$  in the presence of  $A$  consists of a ciphertext-core having the same length as  $P$ , plus an authentication tag. One can view the resulting ciphertext as either the pair (ciphertext-core, tag) or their concatenation (ciphertext-core || tag), the difference being purely how one assembles and parses ciphertexts. This document uses concatenation.

OCB encryption protects the confidentiality of  $P$  and the authenticity of  $A$ ,  $N$ , and  $P$ . It does this using, on average, about  $a + m + 1.02$  blockcipher calls, where  $a$  is the blocklength of  $A$  and  $m$  is the blocklength of  $P$  and the nonce  $N$  is implemented as a counter (if  $N$  is random then OCB uses  $a + m + 2$  blockcipher calls). If  $A$  is fixed during a session then, after preprocessing, there is effectively no cost to having  $A$  authenticated on subsequent encryptions, and the mode will average  $m + 1.02$  blockcipher calls. OCB requires a single key  $K$  for the underlying blockcipher, and all blockcipher calls are keyed by  $K$ . OCB is online. In particular, one need not know the length of  $A$  or  $P$  to proceed with encryption, nor need one know the length of  $A$  or  $C$  to proceed with decryption. OCB is parallelizable: the bulk of its blockcipher calls can be performed simultaneously. Computational work beyond blockcipher calls consists of a small and fixed number of logical operations per call. OCB enjoys provable security: the mode of operation is secure assuming that the underlying blockcipher is secure. As with most modes of operation, security degrades as the number of blocks processed gets large (see [Section 5](#) for details).

For reasons of generality, OCB is defined to operate on arbitrary bit-strings. But for reasons of simplicity and efficiency, most implementations will assume that strings operated on are byte-strings (ie, strings that are a multiple of 8 bits). To promote interoperability, implementations of OCB that communicate with implementations of unknown capabilities should restrict all provided values (nonces, tags, plaintexts, ciphertexts, and associated data) to byte-strings.

The version of OCB defined in this document is a refinement of two prior schemes. The original OCB version was published in 2001 [[OCB1](#)] and was listed as an optional component in IEEE 802.11i. A second version was published in 2004 [[OCB2](#)] and is specified in ISO 19772. The scheme described here is called OCB3 in the 2011 paper describing the mode [[OCB3](#)]; it shall be referred to simply as OCB throughout this document. The only difference between the algorithm of this RFC

and that of the [OCB3] paper is that the tag length is now encoded into the internally formatted nonce. See [OCB3] for complete references, timing information, and a discussion of the differences between the algorithms.

OCB has received years of in-depth analysis previous to its submission to the CFRG, and has been under review by the members of the CFRG for over a year. It is the consensus of the CFRG that the security mechanisms provided by the OCB AEAD algorithm described in this document are suitable for use in providing confidentiality and authentication.

## 2. Notation and Basic Operations

There are two types of variables used in this specification, strings and integers. Although strings processed by most implementations of OCB will be strings of bytes, bit-level operations are used throughout this specification document for defining OCB. String variables are always written with an initial upper-case letter while integer variables are written in all lower-case. Following C's convention, a single equals ("=") indicates variable assignment and double equals ("==") is the equality relation. Whenever a variable is followed by an underscore ("\_"), the underscore is intended to denote a subscript, with the subscripted expression requiring evaluation to resolve the meaning of the variable. For example, when  $i == 2$ , then  $P_i$  refers to the variable  $P_2$ .

$c^i$	The integer $c$ raised to the $i$ -th power.
$\text{bitlen}(S)$	The length of string $S$ in bits (eg, $\text{bitlen}(101) == 3$ ).
$\text{zeros}(n)$	The string made of $n$ zero-bits.
$\text{ntz}(n)$	The number of trailing zero bits in the base-2 representation of the positive integer $n$ . More formally, $\text{ntz}(n)$ is the largest integer $x$ for which $2^x$ divides $n$ .
$S \text{ xor } T$	The string that is the bitwise exclusive-or of $S$ and $T$ . Strings $S$ and $T$ will always have the same length.
$S[i]$	The $i$ -th bit of the string $S$ (indices begin at 1, so if $S$ is 011 then $S[1] == 0$ , $S[2] == 1$ , $S[3] == 1$ ).
$S[i..j]$	The substring of $S$ consisting of bits $i$ through $j$ , inclusive.

`S || T`      String `S` concatenated with string `T` (eg, `000 || 111 == 000111`).

`str2num(S)`      The base-2 interpretation of bitstring `S` (eg, `str2num(1110) == 14`).

`num2str(i,n)`      The `n`-bit string whose base-2 interpretation is `i` (eg, `num2str(14,4) == 1110` and `num2str(1,2) == 01`).

`double(S)`      If `S[1] == 0` then `double(S) == (S[2..128] || 0)`;  
otherwise `double(S) == (S[2..128] || 0) xor (zeros(120) || 10000111)`.

### 3. OCB Global Parameters

To be complete, the algorithms in this document require specification of two global parameters: a blockcipher operating on 128-bit blocks and the length of authentication tags in use.

Specifying a blockcipher implicitly defines the following symbols.

`KEYLEN`              The blockcipher's key length, in bits.

`ENCIPHER(K,P)`      The blockcipher function mapping 128-bit plaintext block `P` to its corresponding ciphertext block using `KEYLEN`-bit key `K`.

`DECIPHER(K,C)`      The inverse blockcipher function mapping 128-bit ciphertext block `C` to its corresponding plaintext block using `KEYLEN`-bit key `K`.

The `TAGLEN` parameter specifies the length of authentication tag used by OCB and may be any value up to 128. Greater values for `TAGLEN` provide greater assurances of authenticity, but ciphertexts produced by OCB are longer than their corresponding plaintext by `TAGLEN` bits. See [Section 5](#) for details about `TAGLEN` and security.

As an example, if 128-bit authentication tags and AES with 192-bit keys are to be used, then `KEYLEN` is 192, `ENCIPHER` refers to the AES-192 cipher, `DECIPHER` refers to the AES-192 inverse cipher, and `TAGLEN` is 128 [[AES](#)].

#### 3.1. Named OCB Parameter Sets and [RFC 5116](#) Constants

The following table gives names to common OCB global parameter sets. Each of the AES variants is defined in [[AES](#)].

+-----+-----+-----+		
Name	Blockcipher	TAGLEN
+-----+-----+-----+		
AEAD_AES_128_OCB_TAGLEN128	AES-128	128
AEAD_AES_128_OCB_TAGLEN96	AES-128	96
AEAD_AES_128_OCB_TAGLEN64	AES-128	64
AEAD_AES_192_OCB_TAGLEN128	AES-192	128
AEAD_AES_192_OCB_TAGLEN96	AES-192	96
AEAD_AES_192_OCB_TAGLEN64	AES-192	64
AEAD_AES_256_OCB_TAGLEN128	AES-256	128
AEAD_AES_256_OCB_TAGLEN96	AES-256	96
AEAD_AES_256_OCB_TAGLEN64	AES-256	64
+-----+-----+-----+		

[RFC 5116](#) defines an interface for authenticated encryption schemes [RFC5116]. [RFC 5116](#) requires the specification of certain constants for each named AEAD scheme. For each of the OCB parameter sets listed above: P\_MAX, A\_MAX, and C\_MAX are all unbounded; N\_MIN is 1 byte and N\_MAX is 15 bytes. The parameter-sets indicating the use of AES-128, AES-192 and AES-256 have K\_LEN equal to 16, 24 and 32 bytes, respectively.

Each ciphertext is longer than its corresponding plaintext by exactly TAGLEN bits, and TAGLEN is given at the end of each name. For instance, an AEAD\_AES\_128\_OCB\_TAGLEN64 ciphertext is exactly 64 bits longer than its corresponding plaintext.

#### 4. OCB Algorithms

OCB is described in this section using pseudocode. Given any collection of inputs of the required types, following the pseudocode description for a function will produce the correct output of the promised type.

##### 4.1. Associated-Data Processing: HASH

OCB has the ability to authenticate unencrypted associated data at the same time that it provides for authentication and encrypts a plaintext. The following hash function is central to providing this functionality. If an application has no associated data, then the associated data should be considered to exist and to be the empty string. HASH, conveniently, always returns zeros(128) when the associated data is the empty string.

Function name:

HASH

Input:

```

    K, string of KEYLEN bits           // Key
    A, string of any length           // Associated data
Output:
    Sum, string of 128 bits           // Hash result

```

Sum is defined as follows.

```

//
// Key-dependent variables
//
L_* = ENCIPHER(K, zeros(128))
L_$ = double(L_*)
L_0 = double(L_$)
L_i = double(L_{i-1}) for every integer i > 0

//
// Consider A as a sequence of 128-bit blocks
//
Let m be the largest integer so that 128m <= bitlen(A)
Let A_1, A_2, ..., A_m and A_* be strings so that
    A == A_1 || A_2 || ... || A_m || A_*, and
    bitlen(A_i) == 128 for each 1 <= i <= m.
    Note: A_* may possibly be the empty string.

//
// Process any whole blocks
//
Sum_0 = zeros(128)
Offset_0 = zeros(128)
for each 1 <= i <= m
    Offset_i = Offset_{i-1} xor L_{ntz(i)}
    Sum_i = Sum_{i-1} xor ENCIPHER(K, A_i xor Offset_i)
end for

//
// Process any final partial block; compute final hash value
//
if bitlen(A_*) > 0 then
    Offset_* = Offset_m xor L_*
    CipherInput = (A_* || 1 || zeros(127-bitlen(A_*))) xor Offset_*
    Sum = Sum_m xor ENCIPHER(K, CipherInput)
else
    Sum = Sum_m
end if

```

#### [4.2.](#) Encryption: OCB-ENCRYPT

This function computes a ciphertext (which includes a bundled authentication tag) when given a plaintext, associated data, nonce and key. For each invocation of OCB-ENCRYPT using the same key K, the value of the nonce input N must be distinct.

Function name:

OCB-ENCRYPT

Input:

K, string of KEYLEN bits // Key  
 N, string of no more than 120 bits // Nonce  
 A, string of any length // Associated data  
 P, string of any length // Plaintext

Output:

C, string of length bitlen(P) + TAGLEN bits // Ciphertext

C is defined as follows.

```
//
// Key-dependent variables
//
L_* = ENCIPHER(K, zeros(128))
L_$ = double(L_*)
L_0 = double(L_$)
L_i = double(L_{i-1}) for every integer i > 0

//
// Consider P as a sequence of 128-bit blocks
//
Let m be the largest integer so that 128m <= bitlen(P)
Let P_1, P_2, ..., P_m and P_* be strings so that
  P == P_1 || P_2 || ... || P_m || P_*, and
  bitlen(P_i) == 128 for each 1 <= i <= m.
  Note: P_* may possibly be the empty string.

//
// Nonce-dependent and per-encryption variables
//
Nonce = num2str(TAGLEN mod 128,7) || zeros(120-bitlen(N)) || 1 || N
bottom = str2num(Nonce[123..128])
Ktop = ENCIPHER(K, Nonce[1..122] || zeros(6))
Stretch = Ktop || (Ktop[1..64] xor Ktop[9..72])
Offset_0 = Stretch[1+bottom..128+bottom]
Checksum_0 = zeros(128)

//
// Process any whole blocks
//
for each 1 <= i <= m
```

```

    Offset_i = Offset_{i-1} xor L_{ntz(i)}
    C_i = Offset_i xor ENCIPHER(K, P_i xor Offset_i)
    Checksum_i = Checksum_{i-1} xor P_i
end for

//
// Process any final partial block and compute raw tag
//
if bitlen(P_*) > 0 then
    Offset_* = Offset_m xor L_*
    Pad = ENCIPHER(K, Offset_*)
    C_* = P_* xor Pad[1..bitlen(P_*)]
    Checksum_* = Checksum_m xor (P_* || 1 || zeros(127-bitlen(P_*)))
    Tag = ENCIPHER(K, Checksum_* xor Offset_* xor L_$) xor HASH(K,A)
else
    C_* = <empty string>
    Tag = ENCIPHER(K, Checksum_m xor Offset_m xor L_$) xor HASH(K,A)
end if

//
// Assemble ciphertext
//
C = C_1 || C_2 || ... || C_m || C_* || Tag[1..TAGLEN]

```

#### 4.3. Decryption: OCB-DECRYPT

This function computes a plaintext when given a ciphertext, associated data, nonce and key. An authentication tag is embedded in the ciphertext. If the tag is not correct for the ciphertext, associated data, nonce and key, then an INVALID signal is produced.

Function name:

OCB-DECRYPT

Input:

K, string of KEYLEN bits	// Key
N, string of no more than 120 bits	// Nonce
A, string of any length	// Associated data
C, string of at least TAGLEN bits	// Ciphertext

Output:

P, string of length bitlen(C) - TAGLEN bits, // Plaintext  
or INVALID indicating authentication failure

P is defined as follows.

```

//
// Key-dependent variables
//

```

```

L_* = ENCIPHER(K, zeros(128))
L_$ = double(L_*)
L_0 = double(L_$)
L_i = double(L_{i-1}) for every integer i > 0

//
// Consider C as a sequence of 128-bit blocks
//
Let m be the largest integer so that 128m <= bitlen(C) - TAGLEN
Let C_1, C_2, ..., C_m, C_* and T be strings so that
  C == C_1 || C_2 || ... || C_m || C_* || T,
  bitlen(C_i) == 128 for each 1 <= i <= m, and
  bitlen(T) == TAGLEN.
  Note: C_* may possibly be the empty string.

//
// Nonce-dependent and per-decryption variables
//
Nonce = num2str(TAGLEN mod 128,7) || zeros(120-bitlen(N)) || 1 || N
bottom = str2num(Nonce[123..128])
Ktop = ENCIPHER(K, Nonce[1..122] || zeros(6))
Stretch = Ktop || (Ktop[1..64] xor Ktop[9..72])
Offset_0 = Stretch[1+bottom..128+bottom]
Checksum_0 = zeros(128)

//
// Process any whole blocks
//
for each 1 <= i <= m
  Offset_i = Offset_{i-1} xor L_{ntz(i)}
  P_i = Offset_i xor DECIPHER(K, C_i xor Offset_i)
  Checksum_i = Checksum_{i-1} xor P_i
end for

//
// Process any final partial block and compute raw tag
//
if bitlen(C_*) > 0 then
  Offset_* = Offset_m xor L_*
  Pad = ENCIPHER(K, Offset_*)
  P_* = C_* xor Pad[1..bitlen(C_*)]
  Checksum_* = Checksum_m xor (P_* || 1 || zeros(127-bitlen(P_*)))
  Tag = ENCIPHER(K, Checksum_* xor Offset_* xor L_$) xor HASH(K,A)
else
  P_* = <empty string>
  Tag = ENCIPHER(K, Checksum_m xor Offset_m xor L_$) xor HASH(K,A)
end if

```

```
//  
// Check for validity and assemble plaintext  
//  
if (Tag[1..TAGLEN] == T) then  
    P = P_1 || P_2 || ... || P_m || P_*  
else  
    P = INVALID  
end if
```

## 5. Security Considerations

OCB achieves two security properties, confidentiality and authenticity. Confidentiality is defined via "indistinguishability from random bits", meaning that an adversary is unable to distinguish OCB-outputs from an equal number of random bits. Authenticity is defined via "authenticity of ciphertexts", meaning that an adversary is unable to produce any valid nonce-ciphertext pair that it has not already acquired. The security guarantees depend on the underlying blockcipher being secure in the sense of a strong pseudorandom permutation. Thus if OCB is used with a blockcipher that is not secure as a strong pseudorandom permutation, the security guarantees vanish. The need for the strong pseudorandom permutation property means that OCB should be used with a conservatively designed, well-trusted blockcipher, such as AES.

Both the confidentiality and the authenticity properties of OCB degrade as per  $s^2 / 2^{128}$ , where  $s$  is the total number of blocks that the adversary acquires. The consequence of this formula is that the proven security disappears when  $s$  becomes as large as  $2^{64}$ . Thus the user should never use a key to generate an amount of ciphertext that is near to, or exceeds,  $2^{64}$  blocks. In order to ensure that  $s^2 / 2^{128}$  remains small, a given key should be used to encrypt at most  $2^{48}$  blocks ( $2^{55}$  bits or 4 petabytes), including the associated data. To ensure these limits are not crossed, automated key management is recommended in systems exchanging large amounts of data [[RFC4107](#)].

When a ciphertext decrypts as INVALID it is the implementor's responsibility to make sure that no information beyond this fact is made adversarially available.

OCB encryption and decryption produce an internal 128-bit authentication tag. The parameter TAGLEN determines how many bits of this internal tag are included in ciphertexts and used for authentication. The value of TAGLEN has two impacts: An adversary can trivially forge with probability  $2^{-\text{TAGLEN}}$ , and ciphertexts are TAGLEN bits longer than their corresponding plaintexts. It is up to

the application designer to choose an appropriate value for TAGLEN. Long tags cost no more computationally than short ones.

Normally, a given key should be used to create ciphertexts with a single tag length, TAGLEN, and an application should reject any ciphertext that claims authenticity under the same key but a different tag length. While the ciphertext core and all of the bits of the tag do depend on the tag length, this is done for added robustness to misuse and should not suggest that receivers accept ciphertexts employing variable tag lengths under a single key.

Timing attacks are not a part of the formal security model and an implementation should take care to mitigate them in contexts where this is a concern. To render timing attacks impotent, the amount of time to encrypt or decrypt a string should be independent of the key and the contents of the string. The only explicitly conditional OCB operation that depends on private data is `double()`, which means that using constant-time blockcipher and `double()` implementations eliminates most (if not all) sources of timing attacks on OCB. Power-usage attacks are likewise out of scope of the formal model, and should be considered for environments where they are threatening.

The OCB encryption scheme reveals in the ciphertext the length of the plaintext. Sometimes the length of the plaintext is a valuable piece of information that should be hidden. For environments where "traffic analysis" is a concern, techniques beyond OCB encryption (typically involving padding) would be necessary.

Defining the ciphertext that results from OCB-ENCRYPT to be the pair  $(C_1 || C_2 || \dots || C_m || C_*, \text{Tag}[1..TAGLEN])$  instead of the concatenation  $C_1 || C_2 || \dots || C_m || C_* || \text{Tag}[1..TAGLEN]$  introduces no security concerns. Because TAGLEN is fixed, both versions allow ciphertexts to be parsed unambiguously.

### **5.1. Nonce Requirements**

It is crucial that, as one encrypts, one does not repeat a nonce. The inadvertent reuse of the same nonce by two invocations of the OCB encryption operation, with the same key, but with distinct plaintext values, undermines the confidentiality of the plaintexts protected in those two invocations, and undermines all of the authenticity and integrity protection provided by that key. For this reason, OCB should only be used whenever nonce uniqueness can be provided with certainty. Note that it is acceptable to input the same nonce value multiple times to the decryption operation. We emphasize that the security consequences are quite serious if an attacker observes two ciphertexts that were created using the same nonce and key values, unless the plaintext and AD values in both invocations of the encrypt

operation were identical. First, a loss of confidentiality ensues because the attacker will be able to infer relationships between the two plaintext values. Second, a loss of authenticity ensues because the attacker will be able to recover secret information used to provide authenticity, making subsequent forgeries trivial. Note that there are AEAD schemes, particularly SIV [[RFC5297](#)], appropriate for environments where nonces are unavailable or unreliable. OCB is not such a scheme.

Nonces need not be secret, and a counter may be used for them. If two parties send OCB-encrypted plaintexts to one another using the same key, then the space of nonces used by the two parties must be partitioned so that no nonce that could be used by one party to encrypt could be used by the other to encrypt (eg, odd and even counters).

## 6. IANA Considerations

The Internet Assigned Numbers Authority (IANA) has defined a registry for Authenticated Encryption with Associated Data parameters. The IANA has added the following entries to the AEAD Registry. Each name refers to a set of parameters defined in [Section 3.1](#).

Name	Reference	Numeric Identifier
AEAD_AES_128_OCB_TAGLEN128	<a href="#">Section 3.1</a>	XX
AEAD_AES_128_OCB_TAGLEN96	<a href="#">Section 3.1</a>	XX
AEAD_AES_128_OCB_TAGLEN64	<a href="#">Section 3.1</a>	XX
AEAD_AES_192_OCB_TAGLEN128	<a href="#">Section 3.1</a>	XX
AEAD_AES_192_OCB_TAGLEN96	<a href="#">Section 3.1</a>	XX
AEAD_AES_192_OCB_TAGLEN64	<a href="#">Section 3.1</a>	XX
AEAD_AES_256_OCB_TAGLEN128	<a href="#">Section 3.1</a>	XX
AEAD_AES_256_OCB_TAGLEN96	<a href="#">Section 3.1</a>	XX
AEAD_AES_256_OCB_TAGLEN64	<a href="#">Section 3.1</a>	XX

## 7. Acknowledgements

The design of the original OCB scheme [[OCB1](#)] was done while Rogaway was at Chiang Mai University, Thailand. Follow-up work [[OCB2](#)] was done with support of NSF grant 0208842 and a gift from Cisco. The final work by Krovetz and Rogaway [[OCB3](#)] that has resulted in this spec was supported by NSF grant 0904380. Thanks go to the many members of the Crypto Forum Research Group (CFRG) who provided feedback on earlier drafts. Thanks in particular go to David McGrew for contributing some text and for managing the RFC approval process,

to James Manger for initiating a productive discussion on tag-length dependency and for greatly improving [Appendix A](#), to Matt Caswell and Peter Dettman for writing implementations and verifying test vectors, and to Stephen Farrell and Spencer Dawkins for their careful reading and suggestions.

## **[Appendix A.](#) Sample Results**

This section gives sample output values for various inputs when using OCB with AES as per the parameters defined in [Section 3.1](#). All strings are represented in hexadecimal (eg, 0F represents the bitstring 00001111).

The following 16 (N,A,P,C) tuples show the ciphertext C that results from OCB-ENCRYPT(K,N,A,P) for various lengths of associated data (A) and plaintext (P). The key (K) has a fixed value, the tag length is 128 bits, and the the nonce (N) increments.

K : 000102030405060708090A0B0C0D0E0F

An empty entry indicates the empty string.

The following algorithm tests a wider variety of inputs. Results are given for each parameter set defined in [Section 3.1](#).

```
K = zeros(KEYLEN-8) || num2str(TAGLEN,8)
C = <empty string>
for i = 0 to 127 do
    S = zeros(8i)
    N = num2str(3i+1,96)
    C = C || OCB-ENCRYPT(K,N,S,S)
    N = num2str(3i+2,96)
    C = C || OCB-ENCRYPT(K,N,<empty string>,S)
    N = num2str(3i+3,96)
    C = C || OCB-ENCRYPT(K,N,S,<empty string>)
end for
N = num2str(385,96)
Output : OCB-ENCRYPT(K,N,C,<empty string>)
```

Iteration  $i$  of the loop adds  $2i + (3 * TAGLEN / 8)$  bytes to  $C$ , resulting in an ultimate length for  $C$  of 22,400 bytes when  $TAGLEN == 128$ , 20,864 bytes when  $TAGLEN == 192$ , and 19,328 bytes when  $TAGLEN == 64$ . The final OCB-ENCRYPT has an empty plaintext component, so serves only to authenticate  $C$ . The output should be:

```
AEAD_AES_128_OCB_TAGLEN128 Output: 67E944D23256C5E0B6C61FA22FDF1EA2
AEAD_AES_192_OCB_TAGLEN128 Output: F673F2C3E7174AAE7BAE986CA9F29E17
AEAD_AES_256_OCB_TAGLEN128 Output: D90EB8E9C977C88B79DD793D7FFA161C
AEAD_AES_128_OCB_TAGLEN96 Output : 77A3D8E73589158D25D01209
AEAD_AES_192_OCB_TAGLEN96 Output : 05D56EAD2752C86BE6932C5E
AEAD_AES_256_OCB_TAGLEN96 Output : 5458359AC23B0CBA9E6330DD
