Transport Layer Security (TLS) Authorization Using KeyNote
<[draft-keromytis-tls-authz-keynote-07.txt](#)>

Status of this Memo

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF), its areas, and its working groups. Note that other groups may also distribute working documents as Internet-Drafts.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

The list of current Internet-Drafts can be accessed at <http://www.ietf.org/ietf/1id-abstracts.txt>.

The list of Internet-Draft Shadow Directories can be accessed at <http://www.ietf.org/shadow.html>.

Code Components extracted from this document must include Simplified BSD License text as described in Section 4.e of the [Trust Legal Provisions](#) and are provided without warranty as described in the BSD License.

Abstract

This document specifies the use of the KeyNote trust-management system as an authorization extension in the Transport Layer

Security (TLS) Handshake Protocol, according to [\[AUTHZ\]](#). Extensions carried in the client and server hello messages confirm that both parties support the desired authorization data types. Then, if supported by both the client and the server, KeyNote credentials are exchanged during the supplemental data handshake message.

1. Introduction

This document describes the identifiers necessary to exchange KeyNote [\[KEYNOTE\]](#) credential assertions inside a TLS [\[TLS1.0\]](#) [\[TLS1.1\]](#) [\[TLS1.2\]](#) exchange. Such credential assertions can authorize the client and/or the server to perform certain actions. In most usage scenarios, the KeyNote credential assertions will be signed by a cryptographic public key [\[RFC2792\]](#). By using the X.509 key and signature encoding [\[X509KEY\]](#), it is possible to add KeyNote-based authorization and policy compliance support to the existing, unmodified X.509 authentication exchange in TLS.

A list of KeyNote credentials (e.g., forming a delegation chain) may be sent as part of the same payload. Alternatively, a URL [\[RFC3986\]](#) pointing to the location of such a list of KeyNote credentials may be provided.

In most scenarios, at least one of these credentials will be issued to the public key of the transmitter of the credentials, i.e., said public key will appear in the ``Licensees'' field of at least one KeyNote credential assertion. The same public key will generally be used by the transmitter of the same credentials to authenticate as part of the TLS exchange. The authentication material (e.g., cryptographic public key) that was used by the transmitter to authenticate in the TLS exchange will be provided to the KeyNote evaluation engine as an ``Action Authorizer''.

2. KeyNote Credential Assertion Lists

The KeyNote Assertion List type definition in the TLS Authorization Data Formats registry is:

```
keynote_assertion_list(TBA)
```

When the `keynote_assertion_list` value is present, the authorization data is a list of KeyNote credential assertions that conforms to the profile in [RFC 2704](#) [\[KEYNOTE\]](#).

A KeyNote assertion list is transmitted inside an `AuthorizationDataEntry` structure as an opaque sequence of 1 - $2^{16}-1$ bytes:

```
opaque KeyNoteAssertionList<1..2^16-1>;
```

When KeyNoteAssertionList is used, the field contains an ASCII-encoded list of signed KeyNote assertions, as described in [RFC 2704 \[KEYNOTE\]](#). The assertions are separated by two '\n' (newline) characters. A KeyNote assertion is a structure similar to a public key certificate; the main difference is that instead of a binding between a name and a public key, KeyNote assertions bind public keys to authorization rules that are evaluated by the peer when the sender later issues specific requests.

When making an authorization decision based on a list of KeyNote assertions, proper linkage between the KeyNote assertions and the public key certificate that is transferred in the TLS Certificate message is needed. Receivers of a KeyNote assertion list should initialize the ACTION_AUTHORIZER variable to be the sender's public key, which was used to authenticate the TLS exchange. If a different authentication mechanism is used, it is the responsibility of the credential issuer to issue the appropriate credentials.

3. KeyNote Credential Assertion List URL

The KeyNote Assertion List URL type definition in the TLS Authorization Data Formats registry is:

```
keynote_assertion_list_url(TBA)
```

A KeyNote Assertion List URL is transmitted inside an AuthorizationDataEntry structure as a URLandHash structure [[AUTHZ](#)].

When the keynote_assertion_list_url value is present, the authorization data is a list of KeyNote assertions as described in [Section 2](#); however the KeyNote assertion list is fetched with the supplies URL. A one-way hash value is provided to ensure that the intended KeyNote credential assertion is obtained.

Implementations that support keynote_assertion_list_url MUST support URLs that employ the http scheme [[HTTP](#)]. These implementations MUST confirm that the hash value computed on the fetched authorization matches the one received in the handshake. Mismatch of the hash values SHOULD be treated as though the authorization was not provided, which will result in a bad_certificate alert [[AUTHZ](#)].

Other schemes may also be supported. When dereferencing these URLs, circular dependencies MUST be avoided. Avoiding TLS when dereferencing these URLs is one way to avoid circular dependencies. Therefore, clients using the HTTP scheme MUST NOT use these TLS extensions if UPGRADE in HTTP [[UPGRADE](#)] is used. For other schemes, similar care must be taken to avoid using these TLS extensions.

4. IANA Considerations

This document requires two new entries in the IANA-maintained TLS Authorization Data Formats registry, `keynote_assertion_list(TBA)` and `keynote_assertion_list_url(TBA)`. This registry is defined in [\[AUTHZ\]](#). The numbers should be allocated from the Specification Required space.

5. Security Considerations

There are no security considerations beyond those discussed in [\[KEYNOTE\]](#), [\[RFC2792\]](#), and [\[AUTHZ\]](#).

[Appendix A](#). Updated TLS Authorization Data Structures

For clarity, this Appendix shows an updated version of the relevant data structures from Section 3.3 in [\[AUTHZ\]](#) with the new entries described in this document. The added elements are denoted with two asterisks ('**') at the end of the respective lines.

```
struct {
    AuthorizationDataEntry authz_data_list<1..2^16-1>;
} AuthorizationData;

struct {
    AuthzDataFormat authz_format;
    select (AuthzDataFormat) {
        case x509_attr_cert:                X509AttrCert;
        case saml_assertion:                SAMLAssertion;
        case x509_attr_cert_url:            URLandHash;
        case saml_assertion_url:            URLandHash;
        case keynote_assertion_list:        KeyNoteAssertionList;    **
        case keynote_assertion_list_url:    URLandHash;                **
    }
} AuthorizationDataEntry;

enum {
    x509_attr_cert(0), saml_assertion(1), x509_attr_cert_url(2),
    saml_assertion_url(3),
    keynote_assertion_list(TBA), keynote_assertion_list_url(TBA), **
    (255)
} AuthzDataFormat;

opaque X509AttrCert<1..2^16-1>;

opaque SAMLAssertion<1..2^16-1>;

opaque KeyNoteAssertionList<1..2^16-1>;    **

struct {
    opaque url<1..2^16-1>;
```

```

    HashAlgorithm hash_alg;
    select (hash_alg) {
        case md5:      MD5Hash;
        case sha1:     SHA1Hash;
        case sha224:   SHA224Hash;
        case sha256:   SHA256Hash;
        case sha384:   SHA384Hash;
        case sha512:   SHA512Hash;
    } hash;
} URLandHash;

enum {
    none(0), md5(1), sha1(2), sha224(3), sha256(4), sha384(5),
    sha512(6), (255)
} HashAlgorithm;

opaque MD5Hash[16];

opaque SHA1Hash[20];

opaque SHA224Hash[28];

opaque SHA256Hash[32];

opaque SHA384Hash[48];

opaque SHA512Hash[64];

```
