Label Distribution Using ARP draft-kompella-mpls-larp-05

Abstract

This document describes extensions to the Address Resolution Protocol to distribute MPLS labels for IPv4 and IPv6 host addresses. Distribution of labels via ARP enables simple plug-and-play operation of MPLS.

Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

The term "server" will be used in this document to refer to an ARP/ L-ARP server; the term "host" will be used to refer to a compute server or other device acting as an ARP/L-ARP client.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at http://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on September 11, 2016.

1. Introduction

This document describes extensions to the Address Resolution Protocol (ARP) [RFC0826] to advertise label bindings for IP host addresses. While there are well-established protocols, such as LDP, RSVP and BGP, that provide robust mechanisms for label distribution, these protocols tend to be relatively complex, and often require detailed configuration for proper operation. There are situations where a simpler protocol may be more suitable from an operational standpoint.

An example is the case where an MPLS Fabric is the underlay technology in a Data Center; here, MPLS tunnels originate from host machines. The host thus needs a mechanism to acquire label bindings to participate in the MPLS Fabric. [TODO-MPLS-FABRIC] describes the motivation for using MPLS as the fabric technology.

Another use-case is Egress Peer Traffic-Engineering (EPE) [I-D.gredler-idr-bgplu-epe]. In EPE, if the host makes the decision to direct packets towards a specific link using MPLS tunneling techniques, there needs to a suitable protocol for the host to acquire MPLS labels from the network.

In both the cases, the mechanism that the host uses to participate in label exchange with the network needs to be simple, and plug-and-play. Existing signaling/routing protocols do not always meet this need. Labeled ARP (L-ARP) is a proposal to fill that gap.

1.1. Approach

ARP is a nearly ubiquitous protocol; every device with an Ethernet interface, from hand-helds to hosts, have an implementation of ARP. ARP is plug-and-play; ARP clients do not need configuration to use ARP. That suggests that ARP may be a good fit for devices that want to source and sink MPLS tunnels, but do so in a zero-config, plug-and-play manner, with minimal impact to their code.

The approach taken here is to create a minor variant of the ARP protocol, labeled ARP (L-ARP), which is distinguished by a new hardware type, MPLS-over-Ethernet. Regular (Ethernet) ARP (E-ARP) and L-ARP can coexist; a device, as an ARP client, can choose to send out an E-ARP or an L-ARP request, depending on whether it needs Ethernet or MPLS connectivity. Another device may choose to function as an E-ARP server and/or an L-ARP server, depending on its ability to provide an IP-to-Ethernet and/or IP-to-MPLS mapping.

2. Overview of Ethernet ARP

In the most straightforward mode of operation [RFC0826], ARP queries are sent to resolve "directly connected" IP addresses. The ARP query is broadcast, with the Target Protocol Address field (see Section 10 for a description of the fields in an ARP message) carrying the IP address of another node in the same subnet. All the nodes in the LAN receive this ARP query. All the nodes, except the node that owns the IP address, ignore the ARP query. The IP address owner learns the MAC address of the sender from the Source Hardware Address field in the ARP request, and unicasts an ARP reply to the sender. The ARP reply carries the replying node's MAC address in the Source Hardware Address field, thus enabling two-way communication between the two nodes.

A variation of this scheme, known as "proxy ARP" [RFC2002], allows a node to respond to an ARP request with its own MAC address, even when the responding node does not own the requested IP address. Generally, the proxy ARP response is generated by routers to attract traffic for prefixes they can forward packets to. This scheme requires the host to send ARP queries for the IP address the host is trying to reach, rather than the IP address of the router. When there is more than one router connected to a network, proxy ARP enables a host to automatically select an exit router without running any routing protocol to determine IP reachability. Unlike regular ARP, a proxy ARP request can elicit multiple responses, e.g., when more than one router has connectivity to the address being resolved. The sender must be prepared to select one of the responding routers.

Yet another variation of the ARP protocol, called 'Gratuitous ARP' [RFC2002], allows a node to update the ARP cache of other nodes in an unsolicited fashion. Gratuitous ARP is sent as either an ARP request or an ARP reply. In either case, the Source Protocol Address and Target Protocol Address contain the sender's address, and the Source Hardware Address is set to the sender's hardware address. In case of a gratuitous ARP reply, the Target Hardware Address is also set to the sender's address.

3. L-ARP Protocol Operation

The L-ARP protocol builds on the proxy ARP model, and also leverages gratuitous ARP model for asynchronous updates.

In this memo, we will refer to L-ARP clients (that make L-ARP requests) and L-ARP servers (that send L-ARP responses). In Figure 1, H1, H2 and H3 are L-ARP clients, and T1, T2 and T3 are IP routers playing the role of L-ARP server. T4 is a member of the MPLS Fabric that may not be an L-ARP server. Within the MPLS Fabric, the

Kompella, et al. Expires September 11, 2016 [Page 4]

usual MPLS protocols (IGP, LDP, RSVP-TE) are run. Say H1, H2 and H3 want to establish MPLS tunnels to each other (for example, they are using BGP MPLS VPNs as the overlay virtual network technology). H1 might also want to talk to a member of the MPLS Fabric, say T (not depicted in the diagram).

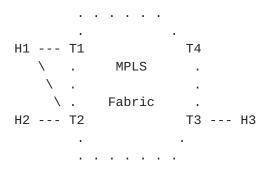

Figure 1

3.1. Setup

In Figure 1, the nodes T1-T4, and those in between making up the "MPLS Fabric" are assumed to be running some protocol whereby they can signal MPLS reachability to themselves and to other nodes (like H1-H3). T1-T3 are L-ARP servers; T4 need not be. H1-H3 are L-ARP clients.

3.2. Egress Operation

A node (say T3) that wants an attached node (say H3) to have MPLS reachability, allocates a label L3 to reach H3, and advertises this label into the MPLS Fabric. This can be triggered by configuration on T3, or via some other protocol. On receiving a packet with label L3, T3 pops the label and send the packet to H3. This is the usual operation of an MPLS Fabric, with the addition of advertising labels for nodes outside the fabric.

3.3. Ingress Operation

A node (say H1, the L-ARP client) that needs an MPLS tunnel to a node (say H3) identified by a host address (either IPv4 or IPv6) broadcasts over all its interfaces an L-ARP query with the Target Protocol Address set to H3. A node (say T1, an L-ARP server) that has MPLS reachability to H3 sends an L-ARP reply with the Source Hardware Address set to its Ethernet MAC address M1, with a new TLV containing a label L1. To send a packet to H3 over an MPLS tunnel, H1 pushes L1 onto the packet, sets the destination MAC address to M1 and sends it to T1. On receiving this packet, T1 swaps the top label with the label(s) for its MPLS tunnel to H3.

Note that H1 broadcasts its L-ARP request over its attached interfaces. H1 may receive several L-ARP replies; in that case, H1 can select any subset of these to send MPLS packets destined to H3. As described later, the L-ARP response may contain certain parameters that enable the client to make an informed choice. However, it is completely a matter of local policy on H1 which of the many responses are used. Some possibilites include, but not limited to,

- o Use the first reply that arrives, and ignore the rest
- o Wait for a certain amount of time, and choose the response carrying the least metric
- o If there is more than one response carrying the least metric, perform load-balancing among them
- o Consult local configuration to select a gateway

If the target H3 belongs to one of the subnets that H1 participates in, and H3 is capable of sending L-ARP replies, H1 can use H3's response to send MPLS packets to H3.

4. Attributes

In addition to carrying a label stack to be used in the data plane, an L-ARP reply carries some attributes that are typically used in the control plane. One of these is a metric. The metric is the distance from the L-ARP server to the destination. This allows an L-ARP client that receives multiple responses to decide which ones to use, and whether to load-balance across some of them. The metric typically will be the IGP shortest path distance from server to the destination; this makes comparing metrics from different servers meaningful.

Another attribute, carried in the LST TLV, is Entropy Label (EL) Capability. This attribute says whether the destination is EL capable (ELC). In Figure 1, if T3 advertises a label to reach H3 and T3 is ELC, T3 can include in its signaling to T1 that it is ELC. In that case, if T1's L-ARP reply to H1 consists of a single label, T1 can set the ELC bit in the label field of the LST TLV. This tells H1 that it may include (below the outermost label) an Entropy Label Indicator followed by an Entropy Label. This will help improve load balancing across the MPLS Fabric, and possibly on the last hop to H3.

5. Client-Server Synchronization

In an L-ARP reply, the server communicates several pieces of information to the client: its hardware address, the MPLS label, Entropy Label capability and metric. Since ARP is a stateless protocol, it is possible that one of these changes without the client knowing, which leads to a loss of synchronization between the client and the server. This loss of synchronization can have several undesirable effects.

If the server's hardware address changes or the MPLS label is repurposed by the server for a different purpose, then packets may be sent to the wrong destination. The consequences can range from suboptimally routed packets to dropped packets to packets being delivered to the wrong customer, which may be a security breach. This last may be the most troublesome consequence of loss of synchronization.

If a destination transitions from entropy label capable to entropy label incapable (an unlikely event) without the client knowing, then packets encapsulated with entropy labels will be dropped. A transition in the other direction is benign.

If the metric changes without the client knowing, packets may be suboptimally routed. This may be the most benign consequence of loss of synchronization.

Standard ARP has similar issues. These are dealt with in two ways: a) ARP bindings are time-bound; and b) an ARP server, recognizing that a change has occurred, can send unsolicited ARP messages ([RFC2002]). Both these techniques are used in L-ARP: the validity of the MPLS label obtained using L-ARP is time-bound; an L-ARP client should periodically resend L-ARP requests to obtain the latest information, and time out entries in its ARP cache if such an update is not forthcoming.

Furthermore, an L-ARP server may update an advertised label binding by sending an unsolicited L-ARP message if any of the parameters mentioned above change. Likewise, an L-ARP server may withdraw its earlier advertisement by sending an unsolicited LARP-NAK message.

<u>5.1</u>. Restart Handling

5.1.1. Server Restart

In order to support graceful restart, the L-ARP server must remember the advertised bindings across restarts. The mechanism that the L-ARP server uses to accomplish this is outside the scope of this document. Some possible mechanisms are, usage of shared memory or non-volatile storage to store bindings. Upon restart, the L-ARP server waits until the LSPs advertised in the previous incarnation are restored. Then, it reconciles the L-ARP bindings with the current state of the LSPs, updating the clients with unsolicted L-ARP replies & NAK for bindings that have undergone changes.

During the above procedure, the client does not really know that the server has restarted. If there were no changes to the LSPs during restart, the client receives no updates. If there were changes, then the client would receive unsolicited updates to the bindings, as it would on a normal change. If the server does not successfully restart, the client's periodic refresh will detect the loss of connectivity and purge out the bindings.

If the L-ARP server does not support graceful restart, it SHOULD withdraw the advertised bindings before shutting down. Unplanned restarts rely on the slower perioidc refresh mechanism for resynchronization.

5.1.2. Client Restart

If the client restarts gracefully, it re-acquires the bindings immediately after restart to learn about any changes.

If the client does not support graceful restart, it leaves the bindings to age out.

5.2. Expedited Reachability Determination

As with other control protocols, the client and server may use data plane liveness detection mechanisms, such as Loss of Signal (LOS) and/or BFD, to expedite detection of loss of connectivity. However, usage of these mechanisms are outside the scope of this document.

6. Applicability

L-ARP can be used between a host and its Top-of-Rack switch in a Data Center. L-ARP can also be used between a DSLAM and its aggregation switch going to the B-RAS. In seamless MPLS terms, L-ARP can be used between an "Access Node" (AN) (e.g., the DSLAM) and its first hop MPLS-enabled device in the context of Seamless MPLS [I-D.ietf-mpls-seamless-mpls]. The first-hop device is part of the MPLS Fabric, as is the Service Node (SN) (e.g., the B-RAS). L-ARP helps create an MPLS tunnel from the AN to the SN, without requiring that the AN be part of the MPLS Fabric. In all these cases, L-ARP can handle the presence of multiple connections between the access device and its first hop devices.

ARP is not a routing protocol. The use of L-ARP should be limited to cases where an L-ARP client has Ethernet connectivity to its L-ARP servers.

7. Backward Compatibility

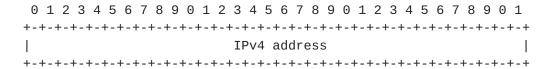

Since L-ARP uses a new hardware type, it is backward compatible with "regular" ARP. ARP servers and clients MUST be able to send out, receive and process ARP messages based on hardware type. They MAY choose to ignore requests and replies of some hardware types; they MAY choose to log errors if they encounter hardware types they do not recognize; however, they MUST handle all hardware types gracefully. For hardware types that they do understand, ARP servers and clients MUST handle operation codes gracefully, processing those they understand, and ignoring (and possibly logging) others.

8. OAM

L-ARP uses standard MPLS OAM procedures defined in [RFC4379] & [RFC6424]. Extending the definitions in section 3.2 of RFC 4379, we use a sub-type of [TO-BE-ASSIGNED-BY-IANA-1] to represent L-ARP IPv4 FEC, and [TO-BE-ASSIGNED-BY-IANA-2] to represent L-ARP IPv6 FEC. The following sub-sections define the format of L-ARP FEC's.

8.1. L-ARP IPv4 FEC

The L-ARP IPv4 FEC is defined as follows:

IPv4 address is the tunnel destination address.

Figure 2: ARP IPv4 FEC

The length of the L-ARP IPv4 FEC is 4 bytes.

8.2. L-ARP IPv6 FEC

The L-ARP IPv6 FEC is defined as follows:

IPv6 address is the tunnel destination address.

Figure 3: ARP IPv6 FEC

The length of the L-ARP IPv6 FEC is 16 bytes.

9. For Future Study

The L-ARP specification is quite simple, and the goal is to keep it that way. However, inevitably, there will be questions and features that will be requested. Some of these are:

- Keeping L-ARP clients and servers in sync. In particular, dealing with:
 - A. client and/or server control plane restart
 - B. lost packets
 - C. timeouts
- 2. Dealing with scale.
- 3. If there are many servers, which one to pick?
- 4. How can a client make best use of underlying ECMP paths?
- 5. and probably many more.

In all of these, it is important to realize that, whenever possible, a solution that places most of the burden on the server rather than on the client is preferable.

These questions (and others that come up during discussions) will be dealt with in future versions of this draft.

10. L-ARP Message Format

Figure 6: MPLS Label Stack Format

Label Stack: Type = TLV-LST; Length = n*3 octets, where n is the number of labels. The Value field contains the MPLS label stack for the client to use to get to the target. Each label is 3 octets. This field is valid only in an L-ARP reply message.

- E-bit: Entropy Label Capable: this flag indicates whether the corresponding label in the label stack can be followd by an Entropy Label. If this flag is set, the client has the option of inserting ELI and EL as specified in [RFC6790]. The client can choose not to insert ELI/EL pair. If this flag is clear, the client MUST NOT insert ELI/EL after the corresponding label.
- Z These bits are not used, and SHOULD be set to zero on sending and ignored on receipt.

```
0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1
Type | Length | Metric (4 octets) ... |
| ... Metric
```

Figure 7: Attribute TLV

Attributes TLV: Type = TLV-ATT; Length = 4 octets. The Value field contains the metric (typically, IGP distance) from the responder to the destination (device with the requested IP address). If the responder is the destination, then the metric value is zero. This field is valid only in an L-ARP reply message.

If other parameters are deemed useful in the ATT TLV, they will be added as needed.

11. Security Considerations

There are many possible attacks on ARP: ARP spoofing, ARP cache poisoning and ARP poison routing, to name a few. These attacks use gratuitous ARP as the underlying mechanism, a mechanism used by L-ARP. Thus, these types of attacks are applicable to L-ARP. Furthermore, ARP does not have built-in security mechanisms; defenses rely on means external to the protocol.

It is well outside the scope of this document to present a general solution to the ARP security problem. One simple answer is to add a TLV that contains a digital signature of the contents of the ARP message. This TLV would be defined for use only in L-ARP messages, although in principle, other ARP messages could use it as well. Such an approach would, of course, need a review and approval by the Security Directorate. If approved, the type of this TLV and its procedures would be defined in this document. If some other technique is suggested, the authors would be happy to include the relevant text in this document, and refer to some other document for the full solution.

12. IANA Considerations

IANA is requested to allocate a new ARP hardware type (from the registry hrd) for HTYPE-MPLS.

IANA is also requested to create a new registry ARP-TLV ("tlv"). This is a registry of one octet numbers. Allocation policies: 0 is not to be allocated; the range 1-127 is Standards Action; the values 128-251 are FCFS; and the values 252-255 are Experimental.

Finally, IANA is requested to allocate two values in the ARP-TLV registry, one for TLV-LST and another for TLV-ATT.

13. Acknowledgments

Many thanks to Shane Amante for his detailed comments and suggestions. Many thanks to the team in Juniper prototyping this work for their suggestions on making this variant workable in the context of existing ARP implementations. Thanks too to Luyuan Fang, Alex Semenyaka and Dmitry Afanasiev for their comments and encouragement.
