SPAKE2, a PAKE
<[draft-ladd-spake2-00.txt](#)>

Status of this Memo

Distribution of this memo is unlimited.

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF), its areas, and its working groups. Note that other groups may also distribute working documents as Internet-Drafts.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

The list of current Internet-Drafts can be accessed at <http://www.ietf.org/ietf/1id-abstracts.txt>.

The list of Internet-Draft Shadow Directories can be accessed at <http://www.ietf.org/shadow.html>.

This Internet-Draft will expire on date.

Abstract

This Internet-Draft describes SPAKE2, a secure, efficient password

based key exchange

Table of Contents

1. Introduction	3
2. Definition of SPAKE2	3
3. Table of points	3
4. Security considerations	4
5. IANA actions	4
6. References	4

[1. Introduction](#)

This document describes a means for two parties that share a password to derive a shared key.

[2. Definition of SPAKE2](#)

Let G be a group in which the Diffie-Hellman problem is hard of prime order p , written additively. Let H be a hash function from arbitrary strings to bit strings of a fixed length. Common choices for H are SHA256 or SHA512. We assume there is a representation of elements of G as byte strings.

$||$ denotes concatenation of strings. We also let $\text{len}(S)$ denote the length of a string in bytes, represented as an eight-byte big-endian number.

We fix two elements M and N as defined in the table in this document for common groups, as well as a generator g of the group.

Let A and B be two parties. We will assume that A and B are also representations of the parties such as MAC addresses or other names (hostnames, usernames, etc). We assume they share an element of \mathbb{Z}_p w . Typically w will be the hash of a user-supplied password, truncated and taken mod p . Protocols using this protocol must define w .

A picks x randomly and uniformly from the integers in $[0, p)$, and calculates $X=xg$ and $T=wM+X$, then transmits T to B .

B selects y randomly and uniformly from the integers in $[0, p)$, and calculates $Y=yg$, $S=wN+Y$, then transmits S to A .

Both A and B calculate a group element K . A calculates it as $x(S-wN)$, while B calculates it as $y(T-wM)$.

Both A and B can now calculate a shared key as $H(\text{len}(A)||\text{len}(B)||\text{len}(S)||\text{len}(T)||A||B||S||T||K)$.

[3. Table of points](#)

[TODO]

4. Security Considerations

A security proof is found in [REF]. Note that the choice of M and N is critical: anyone who is aware of an x such that $xN=M$, or $xg=N$ or M can break the scheme above. The points in the table of points were picked in standard ways to eliminate this risk.

There is no key-confirmation as this is a one round protocol. It is expected that a protocol using this key exchange mechanism provides key confirmation separately if desired.

Elements should be checked for group membership: failure to properly validate group elements can lead to attacks.

5. IANA Considerations

No IANA action is required.
