YANG Based Instance Data Files Format
draft-lengyel-netmod-yang-instance-data-05

Abstract

   There is a need to document data defined in YANG models without the
   need to fetch it from a live YANG server. Data is often needed
   already in design time or needed by groups that do not have a live
   running YANG server available. This document specifies a standard
   file format for YANG Based Instance data, that is data that could be
   stored in a datastore and whose syntax and semantics is defined by
   YANG models. Most important use cases foreseen include documenting
   server capabilities, factory-default settings, or vendor provided
   default configurations.

1. Terminology

   The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT",
   "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and
   "OPTIONAL" in this document are to be interpreted as described in BCP
   14 RFC 2119 [RFC2119] RFC 8174 [RFC8174] when, and only when, they
   appear in all capitals, as shown here.

   Design time: A time during which a YANG model and the implementation
   behind it is created. Sometimes in other documents this period is
   divided into design and implementation time.

   Instance Data Set: A named set of data items that can be used as
   instance data in a YANG data tree.

   Instance Data File: A file containing an instance data set formatted
   according to the rules described in this document.

   Target YANG Module: A YANG module for which the instance data set
   contains instance data, like ietf-yang-library in the examples.

[2](#). Introduction

There is a need to provide instance data defined in YANG models
without the need to fetch it from a live YANG server. Data is often
needed already in design time before the YANG server is implemented
or needed by groups that do not have a live running YANG server
available. To facilitate this off-line delivery of data this
document specifies a standard file format for YANG Based Instance
data, that is data that could be stored in a datastore and whose
syntax and semantics is defined by YANG models.

[2.1](#). Use Cases

We present a number of use cases were Yang based instance data is
needed.

[2.1.1](#). Use Case 1: Early Documentation of Server Capabilites

A YANG server has a number of server-capabilities that are defined in
YANG modules and can be retrieved from the server using protocols
like NETCONF or RESTCONF. YANG server capabilities include

o data defined in ietf-yang-library: YANG modules, submodules,
   features, deviations, schema-mounts, datastores supported
   ([[I-D.ietf-netconf-rfc7895bis](#)])

o alarms supported ([[I-D.ietf-ccamp-alarm-module](#)])

o data nodes, subtrees that support or do not support on-change
   notifications ([[I-D.ietf-netconf-yang-push](#)])

o netconf-capabilities in ietf-netconf-monitoring

While it is good practice to allow a client to query these
capabilites from the live YANG server, that is often not enough.

Often when a network node is released an associated NMS (network
management system) is also released with it. The NMS depends on the
capabilities of the YANG server. During NMS implementation
information about server capabilities is needed. If the information
is not available early in some off-line document, but only as
instance data from the live network node, the NMS implementation will
be delayed, because it has to wait for the network node to be ready.
Also assuming that all NMS implementors will have a correctly
configured network node available to retrieve data from, is a very
expensive proposition. (An NMS may handle dozens of node types.)

Network operators often build their own home-grown NMS systems that
needs to be integrated with a vendor's network node. The operator
needs to know the network node's server capabilities in order to do
this. Moreover the network operator's decision to buy a vendor's
product may even be influenced by the network node's OAM feature set
documented as the Yang server's capabilites.

Beside NMS implementors, system integrators and many others also need
the same information early. Examples could be model driven testing,
generating documentation, etc.

Most server-capabilities are relatively stable and change only during
upgrade or due to licensing or addition or removal of HW. They are
usually defined by a vendor in design time, before the product is
released. It feasible and advantageous to define/document them early
e.g. in a Yang Based Instance Data File.

It is anticipated that a separate IETF document will define in detail
how and which set of server capabilites should be documented.

[2.1.2](). Use Case 2: Preloading Data

There are parts of the configuration that must be fully configurable
by the operator, however for which often a simple default
configuration will be sufficient.

One example is access control groups/roles and related rules. While
a sophisticated operator may define dozens of different groups often
a basic (read-only operator, read-write system administrator,
security-administrator) triplet will be enough. Vendors will often
provide such default configuration data to make device configuration
easier for an operator.

Defining Access control data is a complex task. To help the device
vendor pre-defines a set of default groups (/nacm:nacm/groups) and
rules for these groups to access specific parts of common models
(/nacm:nacm/rule-list/rule).

YANG Based Instance data files are used to document and/or preload
the default configurationp.

[2.1.3](). Use Case 3: Dcoumenting Factory Default Settings

Nearly every YANG server has a factory default configuration. If the
system is really badly misconfigured or if the current configuration
is to be abandoned the system can be reset to this default.

In Netconf the <delete-config> operation can already be used to do this for the startup configuration. There are ongoing efforts to introduce a new, more generic reset operation for the same purpose [I-D.wu-netconf-restconf-factory-restore]

The operator currently has no way to know what the default configuration actually contains. YANG Based Instance data can be used to document the factory default configuration.

3. Instance Data File Format

Two standard formats to represent YANG Based Instance Data are specified based on the XML and JSON encoding. The XML format is based on [RFC7950] while the JSON format is based on [RFC7951]. Later as other YANG encodings (e.g. CBOR) are defined further Instance Data formats may be specified.

For both formats data is placed in a top level auxiliary container named "instance-data-set". The purpose of the container, which is not part of the real data itself, is to carry meta-data for the complete instance-data-set.

The XML format SHALL follow the format returned for a NETCONF GET operation. The <data> anydata (which is not part of the real data itself) SHALL contain all data that would be inside the <data> wrapper element of a reply to the <get> operation. XML attributes SHOULD NOT be present, however if a SW receiving a YANG Based Instance data file encounters XML attributes unknown to it, it MUST ignore them, allowing them to be used later for other purposes.

The JSON format SHALL follow the format of the reply returned for a RESTCONF GET request directed at the datastore resource: {+restconf}/data. ETags and Timestamps SHOULD NOT be included, but if present SHOULD be ignored.

A YANG Based Instance data file MUST contain a single instance data set. Instance data MUST conform to the corresponding target YANG Modules and follow the XML/JSON encoding rules as defined in [RFC7950] and [RFC7951] and use UTF-8 character encoding. A single instance data set MAY contain data for any number of target YANG modules, if needed it MAY carry the complete configuraton and state data set for a YANG server. Default values SHOULD NOT but MAY be included. Config=true and config=false data MAY be mixed in the instance data file. Instance data files MAY contain partial data sets. This means mandatory, min-elements or require-instance=true constrains MAY be violated.

The name of the file SHOULD be of the form:

```
    instance-data-set-name ['@' revision-date] ( '.yid' )

    E.g. acme-router-modules@2018-01-25.yid
```

The revision date is optional. It SHOULD NOT be used if the file is
stored in a version control system (e.g. git) because the change of
file names will break the connection between the different revisions
of the file.

Meta data, information about the data set itself SHALL be included in
the instance data set. This data will be children of the top level
instance-data-set container as defined in the ietf-instance-data YANG
module. Meta data SHALL include:

o Name of the instance data set

Meta data SHOULD include:

o Revision date of the instance data set

o Description of the instance data set. The description SHOULD
   contain information whether and how the data can change during the
   lifetime of the YANG server.

```

           ]
         ]
       }
     }
   }
```

                    Figure 2: JSON Instance Data File example

4. Data Life cycle

   Data defined or documented in YANG Based Instance Data Sets may be
   used for preloading a YANG server with this data, but the server may
   populate the data without using the actual file in which case the
   Instance Data File is only used as documentation.

   While such data will usually not change, data documented by Instance
   Data sets MAY be changed by the YANG server itself or by management
   operations. It is out of scope for this document to specify a method
   to prevent this. Whether such data changes and if so, when and how,
   SHOULD be described either in the instance data file description
   statement or in some other implementation specific manner.

   YANG Based Instance data is a snap-shot of information at a specific
   point of time. If the data changes afterwards this is not
   represented in the instance data set anymore, the valid values can be
   retrieved in run-time via Netconf/Restconf

   Notifications about the change of data documented by Instance Data
   Sets may be supplied by e.g. the Yang-Push mechanism, but it is out
   of scope for this document.

[5](#). Delivery of Instance Data

   Instance data files SHOULD be available without the need for a live
   YANG server e.g. via download from the vendor's website, or any
   other way together with other product documentation.

[6](#). YANG Model

   <CODE BEGINS> file "ietf-yang-instance-data.yang"

      }

      anydata data {
```

```
        mandatory true;
        description "Contains the real instance data.
            The data MUST conform to the relevant YANG Modules.";
      }
    }
  }
}
```

   <CODE ENDS>

7. Security Considerations

   Depending on the nature of the instance data, instance data files MAY
   need to be handled in a secure way. The same type of handling should
   be applied, that would be needed for the result of a <get> operation
   returning the same data.

8. IANA Considerations

   To be completed, all the usual requests for a new YANG module

Appendix A. Open Issues

o If we define metadata per target module, a list of target YAM
   could be included in the metadata. This depends on what
   additional metadata we will include.

o How do we know for which version of the target Yang Module is a
   data set valid? Proposal: One possibility would be to just
   indicate for which module version(s) was the data set last
   updated. This would be a hint about compatibility, but nothing
   more. Maybe we should wait till the YANG versioning work is
   complete/stable. Identifying just one version is way to strict,
   so something enforcing that shall not be used.

o Should we document what YANG features does the instance data set
   implicitly require? Proposal: that is already a use case,
   documenting data from the YANG library.

o Augmenting metadata must be possible. As of now it looks like
   yang-data-ext will solve that. If not, define instance data as
   regular YANG instead of yd:yang-data.

Appendix B. Changes between revisions

   v04 - v05

   o Changed title and introduction to clarify that this draft is only
      about the file format and documenting server capabilities is just
      a use case.

   o Added reference to draft-wu-netconf-restconf-factory-restore

   o Added new open issues.

   v03 - v04

   o Updated changelog for v02-v03

   v02 - v03

   o Updated the document according to comments received at IETF102

   o Added parameter to specify datastore

   o Rearranged chapters

   o Added new use case: Documenting Factory Default Settings

   o Added "Target YANG Module" to terminology

   o Clarified that instance data is a snapshot valid at the time of
      creation, so it does not contain any later changes.

   o Removed topics from Open Issues according to comments received at
      IETF102

   v01 - v02

   o The recommendation to document server capabilities was changed to
      be just the primary use-case. (Merged chapter 4 into the use case
      chapter.)

   o Stated that RFC7950/7951 encoding must be followed which also
      defines (dis)allowed whitespace rules.

   o Added UTF-8 encoding as it is not specified in t950 for instance
      data

   o added XML declaration

   v00 - v01

   o   Redefined using yang-data-ext

   o   Moved meta data into ordinary leafs/leaf-lists
