ISIS Auto-Configuration
draft-liu-isis-auto-conf-01.txt

Status of this Memo

   This Internet-Draft is submitted in full conformance with the
   provisions of BCP 78 and BCP 79.

   Internet-Drafts are working documents of the Internet Engineering
   Task Force (IETF). Note that other groups may also distribute working
   documents as Internet-Drafts. The list of current Internet-Drafts is
   at http://datatracker.ietf.org/drafts/current/.

   Internet-Drafts are draft documents valid for a maximum of six months
   and may be updated, replaced, or obsoleted by other documents at any
   time. It is inappropriate to use Internet-Drafts as reference
   material or to cite them other than as "work in progress."

   This Internet-Draft will expire on August 18, 2014.

Abstract

   This document describes mechanisms for IS-IS to be self-configuring.
   Such mechanisms could reduce the management burden to configure a
   network. One obvious environment that could benefit from these
   mechanisms is IPv6 home network where plug-and-play would be expected.
   Besides home network, some simple enterprise/ISP networks might also
   benefit from the self-configuring mechanisms.

Table of Contents

[1](#). Introduction

This memo describes mechanisms for IS-IS [[RFC1195](#)][RFC5308] to be auto-configuring. Such mechanisms could reduce the management burden to configure a network. One example is home network where plug-and-play would be expected. Besides home network, some simple enterprise/ISP networks might also potentially benefit from the auto-configuring mechanisms.

In addition, this memo defines how such un-configured routers should behave, also limits the risk on existing network using IS-IS (Setcion 3.4 & 3.5).

IS-IS auto-configuration mainly contains the following aspects:

1. IS-IS Default Configuration

2. IS-IS NET self-generation

3. NET duplication detection and resolution

4. Authentication and Wide Metric TLV

[2](#). Design Scope

The auto-configuring mechanisms are not specifically designed based on IPv4 or IPv6.

The auto-configuring mechanisms enabled interfaces are assumed to have a 48-bit MAC address.

The main targeted application scenarios are supposed to be home networks or small enterprise networks .etc. where plug-n-play is expected and complex topology/hierarchy is not needed. Sophisticate requirements from service provider networks are out of scope.

So this document does not provide a complete configuration-free alternative to the IS-IS protocol. The following features of IS-IS are NOT supported by this document:

o Auto-configuring multiple IS-IS processes. The auto-configuration mechanisms only support configuring a single process.

o Route between multiple IS-IS areas. The auto-configuration mechanisms only support routers that are within a single area.

o Auto-configuring multiple operation levels. The auto-configuration mechanisms only support level-1 operation mode.

o This document does not consider interoperability with other routing protocols.

[3]. Protocol Specification

[3.1]. IS-IS Default Configuration

o IS-IS SHOULD be enabled on all interfaces in a router that requires the IS-IS auto-configuration as default. For some specific situations, interface MAY be excluded if it is a clear that running IS-IS on the interface is not required.

o IS-IS interfaces MUST be auto-configured to an interface type corresponding to their layer-2 capability. For example, Ethernet interfaces will be auto-configured as broadcast networks and Point-to-Point Protocol (PPP) interfaces will be auto-configured as Point-to-Point interfaces.

o IS-IS auto-configuration interfaces MUST be configured with level-1.

[3.2]. IS-IS NET Generation

In IS-IS, a router (known as an IS) is identified by an Network Entity Title (NET) which is the address of a Network Service Access Point (NSAP) and represented with an IS-IS specific address format. The NSAP is a logical entity which represents an instance of the IS-IS protocol running on an IS.

The NET consists of three parts. The auto-generation mechanisms of each part are described as the following:

Area address: This field is 1 to 13 octets in length. In IS-IS auto-configuring, this field MUST be 0 in 13 octets length.

System ID: This field follows the area address field, and is 6 octets in length. As specified in IS-IS protocol, this field must be unique among all level-1 routers in the same area when the IS operates at Level 1. In IS-IS auto-configuring, this field SHOULD be the MAC address of one IS-IS enabled interface.

NSEL: This field is the N-selector, and is 1 octet in length. In IS-IS auto-configuring, it must be set to "00".

3.3. IS-IS NET Duplication Detection and Resolution

As described in Section 3, in IS-IS auto-configuring the NETs are
distinguished by the System ID field in which it is a MAC address. So
for IS-IS neighbors' NET duplication, it is equal to MAC address
duplication in a LAN, which means a serious problem that devices need
to be changed. So the NET duplication detection and resolution
mechanism is actually used between non-neighbors which are within
the same IS-IS area.

The rational of IS-IS NET duplication detection and resolution is
described as the following.

3.3.1. Router-Hardware-Fingerprint TLV

The Router-Hardware-Fingerprint TLV is defined in [OSPFv3AC]. This
document re-uses it to achieve NET duplication detection.

```
0                   1                   2                   3
0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
|     Type      |    Length     |
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
|           Router Hardware Fingerprint (Variable)             |
.                                                              .
.                                                              .
.                                                              .
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
         Figure 1 Router-Hardware-Fingerprint TLV Format
```

As defined in [OSPFv3AC], the contents of the hardware fingerprint
should be some combination of CPU ID, or serial number(s) that
provides an extremely high probability of uniqueness. It MUST be
based on hardware attributes that will not change across hard and
soft restarts. The length of the Router-Hardware-Fingerprint is
variable but must be 32 octets or greater.

Note that, since the TLV is to detect MAC address based NET
duplication, the TLV content MUST NOT only use MAC address. MAC
address plus other information are also not recommended to use.

3.3.2. NET Duplication Detection and Resolution Procedures

1) Flood the Router-Hardware-Fingerprint TLVs

When an IS-IS auto-configuration router gets online, it MUST include
the Router-Hardware-Fingerprint TLV in the first originated level-1

LSP. Then all the routers in the area could receive the information
in the TLV.

2) Compare the received Router-Hardware-Fingerprint TLVs

An IS-IS auto-configuring router MUST compare a received self-
originated LSP's Router-Hardware-Fingerprint TLV against its own one.
If they are equal, it means the LSP was indeed originated by the
router itself; if they are not equal, it means some other router has
the same NET originated the LSP, thus there is a NET duplication.

3) Duplication resolution

When NET duplication occurs, the router with the numerically smaller
router hardware fingerprint MUST generate a new NET.

4) Purge the LSPs containing duplicated NET

Before flooding the new NET, the LSP with the prior duplicate NET
MUST be purged. And any IS-IS neighbor adjacencies MUST be
reestablished.

5) Re-join the network with the new NET

After purging the LSPs with the duplicated NET, the router re-join
the IS-IS auto-configuration network with the newly generated NET.

3.4. Authentication TLV

Every IS-IS auto-configuration message MUST include an authentication
TLV (TLV 10, [RFC5304]) with the Type 1 authentication mode
("Cleartext Password") in order to avoid the auto-conf router to
accidentally join an existing IS-IS network which is not intended to
be auto-configured.

This feature is necessary because a low end CPE joining an existing
IS-IS network might seriously break it or cause unnecessary
management confusion.

The cleartext password is specified as "isis-autoconf". Routers that
implement IS-IS auto-configuration MUST use this password as default,
so that different routers could authenticate each other with no human
intervene as default. And routers MUST be able to set manual password
by the users.

3.5. Wide Metric

   IS-IS auto-configuration routers SHOULD support wide metric (TLV 22,
   [RFC5305]). It is recommended that IS-IS auto-configuration routers
   use a high metric value (e.g. 1000000) as default in order to
   typically prefer the manually configured adjacencies rather than the
   auto-conf ones.

3.6. Adjacency Formation Consideration

   ISIS does not require strict hold timers matching to form adjacency.
   But a reasonable range might be needed. Whether we need to specify a
   best practice timers in ISIS-AC is an open question.[TBD].

4. Co-existence with Other IGP Auto-configuration

   If a router supports multiple IGP auto-configuration mechanisms (e.g.
   both IS-IS auto-configuration and OSPF auto-configuration), then in
   practice it is a problem that there should be a mechanism to decide
   which IGP to be used, or even both.

   However, it is not proper to specify choice/interaction of multiple
   IGPs in any standalone IGP auto-configuration protocols. It should be
   done in the CPE level. Currently, there is some relevant work
   emerging, for example, the suggestion from [HOMENET-HNCP] is to have
   the proposed HNCP (Home Network Control Protocol) choose what IGP
   should be used.

5. Security Considerations

   Unwanted routers could easily join in an existing IS-IS auto-
   configuration network by setting the authentication password as
   "isis-autoconf" default value or sniff the cleartext password online.
   However, this is a common security risk shared by other IS-IS
   networks that don't set proper authentication mechanisms. For wired
   deployment, the wired line itself could be considered as an implicit
   authentication that normally unwanted routers are not able to connect
   to the wire line; for wireless deployment, the authentication could
   be achieve at the lower wireless link layer.

   Malicious router could modify the SystemID field to cause NET
   duplication detection and resolution vibrate thus cause the routing
   system vibrate.

6. IANA Considerations

The Router Hardware Fingerprint TLV type code needs an assignment by IANA.

7. Acknowledgments

Many useful comments and contributions were made by Sheng Jiang.

This document was inspired by [OSPFv3AC].
