A YANG Data Model for Abstract Network Topologies
draft-liu-netmod-yang-abstract-topo-00.txt

Abstract

This document describes a concept, a methodology and a YANG data model to (re-)configure abstract topologies, retrieve their states and thus to automate the abstract topology manipulation.

Status of this Memo

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF), its areas, and its working groups. Note that other groups may also distribute working documents as Internet-Drafts.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

The list of current Internet-Drafts can be accessed at
<http://www.ietf.org/ietf/1id-abstracts.txt>

The list of Internet-Draft Shadow Directories can be accessed at
<http://www.ietf.org/shadow.html>

This Internet-Draft will expire on January 1, 2015.

[1. Introduction](#)

Clients of a transport network normally have no visibility into the network's actual topology and resource availability information. There are numerous reasons for this, such as:

- a) Security considerations: network operators are usually reluctant to expose the network's actual topology to its clients;
- b) Transport network, generally speaking, is comprised of network elements that belong to a different layer network than the client devices. Also the internal network routing and traffic engineering advertisements usually contain proprietary information, which the clients cannot interpret, but discarding of which would lead to incorrect assumptions and decisions. This means that the clients cannot use actual network topology and traffic engineering information even if said information is available;
- c) Scalability considerations: clients do not want to know any transport network information that is not related to the services provided to the clients.

Liu

[Page 2]

On the other hand the clients need to influence to certain extent on the way the services provided to them are routed across the transport network: some services, for example, need to be as disjoint from each other as possible because they support various network failure protection schemes provisioned in the client layer network; others, on the contrary, need to be co-routed and share fate as much as possible; placement of some services needs to be optimized based on the lowest cost criteria, while other service paths need to be selected to have best optical signal quality or delay characteristics, and so forth.

Different approaches exist to allow for the clients to affect the placement of provided for them services on the transport network under conditions of no visibility into the actual transport network topology and resource availability information. For example, [GMPL-UNI] architecture allows for clients signaling their service routing policies/preferences within the service setup and modify messages and mandates the network path computers to honor said policies/preferences during the service path selection. There are also control plane based (e.g. [GMPLS-ENNI]) and SDN architectures that require the network to expose abstract topologies. Such topologies are decoupled from the network actual topologies and are provided on per client group/VPN/tenant basis. The abstract topologies are supposed to be fully understandable by the clients and contain sufficient information for the client path computers to select service paths according to the client policies. The service paths so selected in terms of abstract topology elements could be signaled or otherwise conveyed within service setup/modify requests to the transport network system responsible for the service provisioning.

One problem with the abstract topologies exposed to the clients is their static nature. The abstract topologies are usually manually configured based on the transport network operator policies. This entails tedious error-prone configuration. This also does not allow for the clients to have a say as to how the abstract topologies exposed to them should look like, which elements (nodes, links) it should contain, what the parameters (e.g. link bandwidth, SRLGs, etc.) are, and so forth. The problem becomes especially profound in case the clients requirements with respect to the abstract topologies change over time and/or depend on particular week, day, time of the day, etc. It is highly desirable to have a data model understood and supported by the transport network and all its potential clients that would allow for the clients to dynamically (re-)configure the abstract topologies exposed to them in real time. This document introduces a data model written in YANG, that allows for the clients using NETCONF and/or RESTCONF protocols to (re-)configure abstract

topologies, retrieve their data state and, thus, to automate the abstract topology manipulation.

[1.1. Terminology](#)

The keywords "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [BCP 14](#), [[RFC2119](#)].

The following terms are defined in [[RFC6020](#)] and are not redefined here:

- o augment
- o data model
- o data node

[2. Abstract network topology model overview](#)

This document defines the YANG module "abstract-topology", which has the following structure:

```
module: abstract-topology
augment /nt:network-topology/nt:topology/nt:topology-types/l3t:l3-
unicast-igp-topology:
    +-rw abstract!
augment /nt:network-topology/nt:topology/nt:node/nt:termination-
point/l3t:igp-termination-point-attributes:

3. Usage Example

Figure 1 shows an example of abstract network topology. This topology consists of four nodes at the physical layer: E, F, G, and H, which are connected by four physical links: <E, F>, <F, G>, <G, H>, and <E, H>. Nodes E and F are grouped into a virtual node VN1; nodes G and H are grouped into a virtual node VN2. There is a virtual link from node E in VN1 to node G in VN2.

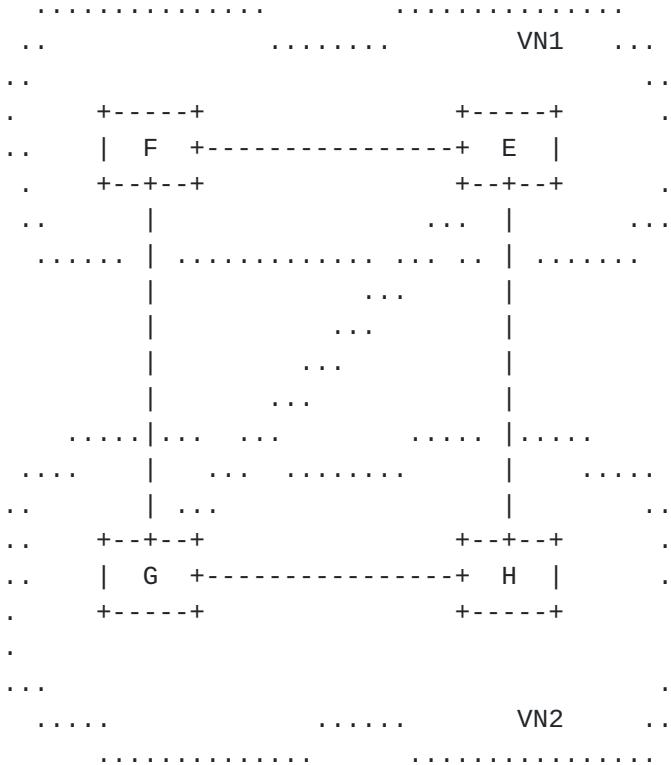

Figure 1 Example of Abstract Network Topology

The JSON encoded configuration example for such a topology can be as following:

```
{  
    "network-topology": {  
        "topology": [  
            {  
                "topology-id": "ODUK",  
                "topology-types": {  
                    "l3-unicast-igp-topology": {  
                        "abstract": {}  
                    }  
                },  
                "node": [  
                    {  
                        "node-id": "VN1",  
                        "termination-point": [  
                            {  
                                "tp-id": "E#CH-1-5-NE",  
                                "igp-termination-point-attributes": {

<CODE ENDS>

5. Security Considerations

The abstract protocol used for sending the topology data MUST support authentication and SHOULD support encryption. The data-model by itself does not create any security implications.
