Problem Statement of BIER IPv6 Encapsulation
draft-mcbride-bier-ipv6-problem-statement-01

Abstract

The BIER WG has a charter item to work on mechanisms which use BIER natively in IPv6. This document is intended to help the WG with this effort by describing the problem space of transporting packets, with Bit Index Explicit Replication (BIER) headers, in an IPv6 environment. There will be a need to send IPv6 payloads, to multiple IPv6 destinations, using BIER. There have been several proposed solutions in this area. But there hasn't been a document which describes the problem and why this may be necessary. The goal of this document is to describe the BIER IPv6 problem space, basic use cases, why new solutions may be needed and briefly summarize some of the proposed solutions.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <https://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on September 9, 2019.

1. Introduction

Bit Index Explicit Replication (BIER) [[RFC8279](#)] is an architecture that provides optimal multicast forwarding, without requiring intermediate routers to maintain per-flow state, through the use of a multicast-specific BIER header. [[RFC8296](#)] defines two types of BIER encapsulation to run on physical links: one is BIER MPLS encapsulation to run on various physical links that support MPLS, the other is BIER Ethernet encapsulation to run on ethernet links, with an ethertype 0xAB37. This document describes using BIER in non-MPLS IPv6 environments. We explain the problem space of transporting IPv4/IPv6 multicast payloads, from an IPv6 router (BFIR) to multicast IPv6 destinations (BFERs), using BIER. This can include native IPv6 encapsulation and generic tunneling. There have been several proposed solutions in this area. But there hasn't been a document which describes the problem and why this may be necessary. The goal

This basic scenario depicts the need to replicate bier packets from a BFIR to BFERs across an IPv6 core. The IPv6 environment may include

a variety of link types, may be entirely IPv6, may be dual stack or any type of combination which includes IPv6. Regardless of the environment, there are times when a BIER header, including the BIER bitstring used to determine the set of BIER forwarding egress routers, will need to traverse a IPv6 domain. The ways in which BIER will function in an IPv6 environment is the problem that needs to be solved. [RFC8354] lists some good IPv6 related use cases which we will similarly reference in this document.

3.1. BIERv6 for Access Network

Access networks deliver a variety of types of multicast video traffic from the service provider's network to the home (or Enterprise) environment and from the home towards the service provider's network.

There will be a need to send traffic from the IPv4 access towards the service provider's IPv6 network and vice versa. A packet could be mapped into a providers IPv6 network through the use of a BIERv6 header. The access devices would not need to know specific details about the packet to perform this mapping; instead the access device would only need to know how to process a BIER header unless there is end to end IPv6.

3.2. BIERv6 for Data Center

Some Data Center operators are transitioning their Data Center infrastructure from IPv4 to native IPv6 only, in order to cope with IPv4 address depletion and to achieve larger scale. In such environment, BIERv6, can be used to natively steer multicast data across an IPv6 data center.

3.3. BIERv6 for Core Networks

While the overall amount of traffic offered to the network continues to grow and considering that multiple types of traffic with different characteristics and requirements are quickly converging over single network architecture, the network operators are starting to face new challenges.

Some operators are currently building, or plan to build in the near future, an IPv6 only native infrastructure for their core network. Having a native BIERv6 infrastructure will help maintain simplicity of the network and reduce state versus traditional IP Multicast.

3.4. Implications for BIER in SRv6

The Source Packet Routing in Networking (SPRING) architecture describes how Segment Routing can be used to steer packets through an IPv6 or MPLS network using the source routing paradigm. [RFC8354] focuses on use cases for Segment Routing in an IPv6 only environment, something which is equally important for BIER in an IPv6 only environment.

4. Example Proposed Solutions

Although this is not a solutions document it should be helpful to list the various proposed solutions, without addressing the benefits of one over another, to help understand the problem more clearly. The following are solutions that have been proposed to solve BIER in v6 environments.

As illustrated in these examples, the BIER header, or the BitString, may appear in the IPv6 Header, IPv6 Extension Header, IPv6 Payload, or IPv6 Tunnel Packet:

4.1. BIER-ETH encapsulation in IPv6 networks

```

+-----+-----+-----+
| Ethernet | BIER header | payload
| (ethType = | (BIFT-id, ...) |
| 0xAB37)   |         |
|         | Next Header |
+-----+-----+-----+
```

BIER-ETH encapsulation (BIER header for Non-MPLS networks as defined in [RFC8296]) can be used to transport the multicast data in the IPv6 network by encapsulating the multicast user data payload within the BIER-ETH header. However, using BIER-ETH in IPv6 networks is not considered to be a native IPv6 solution which utilizes the IPv6 header to forward the packet. Below listed are some of the properties of BIER-ETH encapsulation which could be seen as the reasons for the same,

- o BIER-ETH is not agnostic to the underlying (L2) data link type. It can be deployed only in the networks with Ethernet data link and cannot be deployed in an network which deploys any other data link types. Use of BIER-ETH in IPv6 networks might also result in using different BIER encapsulations, when BIER is used as a E2E multicast transport across a larger heterogeneous IPv6 networks with different data link types used in different layers of the network.

- o BIER-ETH in IPv6 networks is considered similar to 6PE solution where-in the multicast user data packet is encapsulated with-in the BIER-MPLS header.
- * It is worth noting that the only major difference between BIER-MPLS and BIER-Non-MPLS header is that BIER-MPLS uses downstream assigned MPLS label while BIER-Non-MPLS header uses a domain-wide-unique BIFT-id. While the use of domain-wide-unique BIFT-id in BIER-ETH header takes away the complexity of allocation and state maintenance from the network, it still requires some sort of ID (similar to label) to identify the application context after the decapsulation of BIER header (example: MVPN VRF Label). Encoding of such an ID/LABEL before encapsulating the multicast user data payload with BIER-ETH header cannot be avoided.
- * The absence of an IPv6 header, and the optional IPv6 extension headers, deprives BIER of some of the useful cases (ex: Use of IPv6 address for identification of network function or service mapping) that is otherwise possible in native IPv6 encapsulation which utilizes a IPv6 header.
- * Tunneling of BIER packets is one common technique used for FRR, to tunnel over BIER incapable nodes etc. While it is possible for the BIER-ETH encapsulated packet to be further encapsulated within a GRE6 or SRv6, etc tunnel, it might not be possible to parse and decapsulate different types of tunnel headers and forward the BIER packet completely in hardware fast path similar to the label stack processing in BIER-MPLS networks. It would be useful to select an encapsulation which could help in processing the tunnel and BIER header and make the forwarding decision completely in hardware fast path, which is lacking in BIER-ETH encapsulation if chosen to be deployed in pure IPv6 networks.

4.2. Encode Bitstring in IPv6 destination address

```
+-----+-----+
| IPv6 header | payload
| (BitString in |
| DA lower bits)|
| Next Header |
+-----+-----+
```

As described in [[I-D.pfister-bier-over-ipv6](#)], The information required by BIER is stored in the destination IPv6 address. The BIER BitString is encoded in the low-order bits of the IPv6 destination address of each packet. The high-order bits of the IPv6 destination

address are used by intermediate routers for unicast forwarding, deciding whether a packet is a BIER packet, and if so, to identify the BIER Sub-Domain, Set Identifier and BitString length. No additional extension or encapsulation header is required. Instead of encapsulating the packet in IPv6, the payload is attached to the BIER IPv6 header and the IPv6 protocol number is set to the type of the payload. If the payload is UDP, the UDP checksum needs to change when the BitString in the IPv6 destination address changes.

4.3. Add BIER header into IPv6 Extension Header

```
+-----+-----+-----+
| IPv6 header | IPv6 Ext header | payload
|(Multicast DA) | (BIER header in |
|               | TLV Type = X) |
| Next Header  | Next Header  |
+-----+-----+-----+
```

According to [\[RFC8200\]](#) In IPv6, optional internet-layer information is encoded in separate headers that may be placed between the IPv6 header and the upper-layer header in a packet. There is a small number of such extension headers, each one identified by a distinct Next Header value. An IPv6 packet may carry zero, one, or more extension headers, each identified by the Next Header field of the preceding header. Extension headers (except for the Hop-by-Hop Options header) are not processed, inserted, or deleted by any node along a packet's delivery path, until the packet reaches the node (or each of the set of nodes, in the case of multicast) identified in the Destination Address field of the IPv6 header. The Hop-by-Hop Options header is not inserted or deleted, but may be examined or processed by any node along a packet's delivery path, until the packet reaches the node (or each of the set of nodes, in the case of multicast) identified in the Destination Address field of the IPv6 header. The Hop-by-Hop Options header, when present, must immediately follow the IPv6 header. Its presence is indicated by the value zero in the Next Header field of the IPv6 header.

Two of the currently-defined extension headers are the Hop-by-Hop Options header and the Destination Options header which carry a variable number of type-length-value (TLV) encoded "options".

In [\[I-D.xie-bier-ipv6-encapsulation\]](#) an IPv6 BIER Destination Option is carried by the IPv6 Destination Option Header (indicated by a Next Header value 60). It is initialized in a packet sent by an IPv6 BIER router to inform the following BIER routers in an IPv6 BIER domain to replicate to destination BIER routers hop-by-hop. BIER is generally a hop-by-hop and one-to-many architecture and it is required for a

BIER IPv6 encapsulation to include the BIER Header ([[RFC8296](#)]) as an IPv6 Extension Header, to pilot the hop-by-hop BIER replication.

Hop by hop Options Headers may be considered. The Hop-by-Hop Options header is used to carry optional information that may be examined and processed by every node along a packet's delivery path. The Hop-by-Hop Options header is identified by a Next Header value of 0 in the IPv6 header.

Defining New Extension Headers and Options may also be considered, if the IPv6 Destination Option Header is not good enough and new extension headers can solve the problem better.

Such proposals may include requests to IANA to allocate a "BIER Option" code from "Destination Options and Hop-by-Hop Options", and/or a "BIER Option Header" code from "IPv6 Extension Header Types".

[4.4.](#) Transport BIER as IPv6 payload

+-----+	+-----+	+-----+
IPv6 header	IPv6 Ext header	BIER Hdr + payload
	(optional)	as IPv6 payload
Next Header	Next Header = X	
+-----+	+-----+	+-----+

There is a proposal for a transport-independent BIER encapsulation header which is applicable regardless of the underlying transport technology. As described in [[I-D.xu-bier-encapsulation](#)] and [[I-D.zhang-bier-bierin6](#)], the BIER header, and the payload following it, can be combined as an IPv6 payload, and be indicated by a new Upper-layer IPv6 Next-Header value. A unicast IPv6 destination address is used for the replication and changes when replicating a packet out to a neighbor.

Such proposals may include a request to IANA to allocate an IPv6 Next-Header code from "Assigned Internet Protocol Numbers".

[4.5.](#) Tunneling BIER in a IPv6 tunnel

+-----+	+-----+	+-----+	+-----+
IPv6 header	IPv6 Ext header	GRE header	
	(optional)		BIER Hdr +
			payload as GRE
Next Header	Next Header	Proto = X	Payload
+-----+	+-----+	+-----+	+-----+

A generic IPv6 Tunnel could be used to encapsulate the bier packet within an IPv6 domain.

GRE is a mechanism by which any ethernet payload can be carried by an IP GRE tunnel due to the 16-bits 'Protocol Type' field. Both IPv4 and IPv6 can be used to carry GRE. The Ethernet type codepoint 0xAB37, defined for BIER, can be used in a GRE header to indicate the subsequent BIER header and payload in an IPv6 network.

UDP-based tunneling is another mechanism which uses a specific UDP port to indicate a UDP payload format. Both IPv4 and IPv6 can support UDP. Such UDP-based tunnels can be used for BIER in a IPv6 network by defining a new UDP port to indicate the BIER header and payload.

5. Suggested Requirements

This is not a requirements document and we may eventually remove this section. We will, however, summarize some of the "requirements", that have been suggested on the BIER email list, to help further understand the problem. At a minimum, this may serve as a kick start to a requirements draft if one is deemed necessary by the WG:

The solution should be agnostic to the underlying L2 data link type.

The solution should not require hop-by-hop modification of the IP destination address field.

The solution should not require the BFRs to inspect layer 4 or require any changes to layer 4.

The solution should not allow a multicast address to be put in the IP source address field.

The solution should not assume that bits never get set incorrectly.

The solution should not require changes in source address filtering procedures.

The solution should be possible to be used to support the entire BIER architecture.

The solution should avoid having to use different encapsulation types, or use complex tunneling techniques, to support BIER as a E2E multicast transport.

The solution should enable the processing and forwarding of BIER packets in hardware fast path.

6. IANA Considerations

Some BIERv6 encapsulation proposals do not require any action from IANA while other proposals require new BIER Destination Option codepoints from IPv6 sub-registries or require new IP Protocol codes. This document, however, does not require anything from IANA.

7. Security Considerations

There are no security issues introduced by this draft.

8. Acknowledgement

Thank you to Eric Rosen for his listed set of requirements on the bier wg list.
