## Abstract

The Media Objects Markup Language (MOML) is a modular and extensible language to define media processing objects which execute on media servers. The base language defines a set of primitive media objects (called primitives) and provides tools to group primitives together and specify how they interact with each other. Clients use the base MOML, or extend MOML, to create precisely tailored media processing objects which may be used as parts of application interactions with users or conferences or to transform media flowing internal to a media server. IVR is an example of an application interaction with a user.

# **1**. Introduction

This document describes a markup language to configure and define media resource objects within a media server. The language allows the definition of sophisticated and complex media processing objects which may be used for application interactions with users, i.e. as part of a user dialog, or as media transformation operations. Media Objects Markup Language (MOML) itself does not specify a language suitable for constructing complete user interfaces as does VoiceXML [7]. Rather, it defines a language from which individual pieces of a dialog may be specified.

MOML is not a standalone language but will generally be used in conjunction with other languages such as the Media Sessions Markup Language (MSML) [8] or protocols such as the Session Initiation Protocol (SIP). MSML is used to invoke and control many different services on a media server and to manipulate the flow of media

Saleem & Sharratt

streams within a media server. SIP is used to establish media sessions and there are conventions to use the SIP Request-URI to invoke common media server services [9].

MOML has both a framework, which describes the composition of media resource objects, and the definition of an initial set of primitive media resource objects. The following sections describe the structure and usage of MOML followed by sections defining all of the MOML XML elements.

Simple media resources and their composition into more complex operations is a central concept of this specification. This concept is used to precisely define the required behaviors. It is not meant to imply that media servers must be implemented from the same building blocks used to describe the behavior.

### 2. Conventions used in this document

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in <u>RFC 2119</u> [7 (Bradner, S., Key words for use in RFCs to Indicate Requirement Levels, March 1997.)].

#### 3. Overview

MOML is an XML [4] language for composing complex media objects from a vocabulary of simple media resource objects called primitives. It is primarily a descriptive or declarative language to describe media processing objects.

MOML is intended to be used in different environments. As such, the language itself does not define how MOML is used. Each environment in which MOML is used must define how it is used, the set of services provided and the mechanism for passing information between the environment and MOML. The specific mechanisms used to realize the interface between MOML and its environment are platform specific.

This specification defines using MOML with directly with SIP. The Media Session Markup Language [8] is an example of another environment which uses MOML.

MOML provides two models for access to media resources and service creation building blocks. Both models MAY be used in conjunction with each other in a complementary manner. The first model (referred to as Media Primitives and Composites ) contains media primitives (such as digit collection and announcements) and composite functions (such as play and collect combined as a single operation). The second model (referred to as Media Groups allows the ability to define complex

Saleem & Sharratt

customized interactions, via event passing mechanisms, between media primitives, if required.

Media Primitives and Composites

Media Primitives <dtmf> or <collect> DTMF digit collection

<play> Playing of Announcements <dtmfgen>

Generation of DTMF digits <record>

Media recording

Media Composites <collect> Supports play and collect operation. Composite function with inclusion of play. <record> Supports play and record operation. Composite function with inclusion of play.

Media Groups

<group>

Allows grouping of media primitives for parallel execution, with an event exchange mechanism between the media primitives to achieve customized media operations. All the above media primitive elements are accepted within the group.

Following operations MUST be supported using elements described above using either the Media Primitive model or the Media Group model.

Announcement only	<play></play>
Collection only	
Recording only	<dtmf> or <collect></collect></dtmf>
Recording only	<record></record>
Play and Collect	<collect> <play></play> </collect>
Play and Record	<record></record>

<play/>
</record>

MOML MAY be used to simply expose primitive media resource objects but will be used more often to describe dialog operations and media transformation objects which can be controlled via user interaction.

MOML does not contain any computation or flow control constructs. There are no results automatically generated when media operations complete. Results MUST be explicitly requested using a <send> or <exit> element within the definition of the MOML object.

## 3.1 Primitives

Primitives perform a single function on a media stream such as generating audio, recognizing speech or DTMF, or adjusting the gain. They may be composed so that primitives execute concurrently. Primitives not composed for concurrent execution MUST simply execute sequentially in the order they occur in a MOML document. All concurrently executing primitives in the same MOML object (defined in one MOML document) MAY interact with each other through events.

Currently all primitives use audio media but primitives for text and video will be defined in a future version of this specification. Primitives can roughly be considered to fall into one of three descriptive categories.

- recognizers have a media input but no output. They allow different things within a media stream to be recognized or detected and for events to be generated based upon received media.
- o transformers have one media input and output and may send and receive events;
- o sources and sinks generate or consume media. They have either a media input or a media output but not both. They may receive and generate events.
- o composites combine underlying primitives to provide higherlevel user interaction, without the need for specific event based exchange between the primitives. The composite elements provide a simpler mechanism for more commonly used services, such as play and collect or play and record.

Primitives may define different media processing behavior (states) based upon the events which they receive. Primitives which support different processing states must define their default starting state

and should support the "initial" attribute to allow that state to be specified when the primitive is instantiated. All primitives must support the "terminate" event class.

The following types of primitives are defined within this specification:

Recognizers	Transformers	Source/Sink	Composites
dtmf faxtone speech vad	agc clamp gain gate relay	play record dtmfgen faxsend faxrcv	collect record

Primitives have shadow variables, similar to those within VoiceXML [7], which are automatically assigned values when the primitives are used. Upon initialization of a MOML context, all shadow variables have the string value "undefined". Each primitive has its own instance of shadow variables which are global in scope to the entire MOML context.

Names SHOULD be assigned to individual primitives when more than one primitive of the same type is used within one MOML document. Shadow variables are overwritten if the primitive has not been named and is instantiated a second time.

Shadow variables cannot be modified under user control. They may be returned from the MOML context using the <send> element.

## 3.2 Groups

Primitives are composed for concurrent execution by placing them within a <group> element. Groups define how media flows between multiple concurrently executing primitives. They have one or more inputs and one or more outputs. A <group> represents the declaration of a complex media processing operation. The event interaction between primitives (see the following sub-section) is defined within the context of one or more groups. However groups themselves do not scope events, they simply define that primitives are concurrently executing and a primitive must be executing in order to receive an event.

Placing primitives within a group structure is an optional feature of this specification. It allows for complex services to created using the event exchange mechanism between the primitives. For simpler services, such as play/collect or play/record, the use of group mechanism is not necessary. These basic services MAY be accomplished using composites and primitives instead.

Saleem & Sharratt

Internet-draft Media Objects Markup Language (MOML) October 2005

Groups may also be used to describe media objects which transform a media stream while optionally allowing application or user control of the transformation. For example a gain control could be defined which responds to user speech or DTMF input. In this case a recognition primitive would send events to a gain control primitive.

Groups have one attribute which defines the media flow within them. They also have a dimension which defines how many media inputs and outputs they have. Currently dimensions of 1 and 2 are supported based upon the group topology. These correspond to a group with one input and one output and a group with two inputs and two outputs.

Media flow to and from the primitives within the group is based upon a topology attribute of the <group> element. This differs from a similar mechanism in Media Policy Manipulation in the Conference Policy Control Protocol [3] which explicitly defined connections. The topology attribute defines a topology schema and implies the group dimension.

There are several common ways in which primitives are often connected together. A schema provides a convenient template which can be applied to multiple primitives without having to define all of the individual media relationships. The following two schemas are initially defined for 1 dimensional groups:

- o parallel: specifies that media sent to the group is sent to every primitive which has an input. The group bridges the output from every primitive which has an output into a single common group output;
- o serial: specifies that the first primitive listed in the group receives the media sent to the group. Its output is to be connected to the input of the next primitive defined within the group and so on until the last primitive within the group which becomes the group output.

Groups with these topologies are shown in the two diagrams below. The group on the left has a parallel topology and that on the right has a serial topology.

More complex media flows MAY be created by nesting groups of serial and parallel topologies within each other. For example, the diagram

Saleem & Sharratt Expires - April 2006

below has a group with a serial topology nested within a star topology.

/----> P1 -----\ Gs(in) +-> Gp(in) --> P2 --> P3 --> Gp(out) -+> Gs(out)

This combination could be used to create record operation where DTMF was to be clamped from the recording itself, but a DTMF key press is still used to stop the recording. In this case, P1 would be a DTMF recognizer, P2 would be a clamp primitive, and P3 a recorder as shown by the following example. This example omits child elements and attributes not concerned with the core concept. The following section discusses sending events and the details of each of the primitives is defined in section 4.

```
<group topology="parallel">
   <dtmf/>
  <group topology="serial">
      <clamp/>
      <record/>
   </group>
</group>
```

A single schema, "fullduplex" is defined for a two dimensional group. A full-duplex two dimensional group is has exactly two immediate children. Those children may be primitives or other one dimensional groups. A "fullduplex" group must only be used as the top most group and must not be nested. Each primitive (P1) and group (G2) becomes half of the full-duplex group as shown in the diagram below.

G-A(in1) +-> G2 --> G-B(out1)

G-A(out2) <-- P1 <-+ G-B(in2)

Full duplex groups are symmetrical when both halves are the same. They are asymmetrical when they differ. Asymmetric groups need to have a name associated with each side. The left side is defined as the input of the first child of the full-duplex group combined with the output of the second child. The right side is reverse. These sides were labeled A and B respectively in the preceding diagram.

An example of a full-duplex group is the user operated gain control mentioned at the beginning of this sub-section. The gain should operate on the audio which a user hears, but the gain is controlled by recognizing things such as DTMF or spoken commands in media which the user originates. The following shows the XML tag grouping which would accomplish this and corresponds to the media flow shown in the diagram above. If the user's audio is not required for anything other

Saleem & Sharratt

Expires - April 2006

[Page 10]

than control of the gain, then the <relay> is not required and the internal group could be omitted. A complete XML description for this is included in the examples section.

```
<group topology="fullduplex">
  <group topology="parallel">
      <dtmf/>
      <relay/>
  </group>
  <qain/>
</group>
```

Primitives within a group MUST begin concurrently but MAY finish asynchronously based upon events which they receive or their task completes. A group MUST terminate when all of the primitives within it have completed. If the group contains a <groupexit> element, then the contents of that element MUST be executed as part of group termination.

A group itself MAY receive a terminate event requesting termination. A terminate event sent to the group causes a terminate event to be sent to each of its currently active primitives. The <groupexit> element is not executed until all primitives have processed their respective terminate events.

#### 3.3 Events

Events provide the mechanism for primitives to interact with each other and for a MOML context to interact with its external environment. The external environment is defined by the way in which a MOML context has been invoked. This will often be through MSML but other languages and protocols such as SIP may also be used.

Every primitive and group conceptually implements their own event queue. Events sent to them get placed into their associated queue. Events are removed from their queues and processed in order. Primitives within a group conceptually have their own thread of execution. Due to the asynchronous nature of servicing events from multiple queues, it cannot be assumed that several events sent in sequence to different queues, will be processed in the order in which they were sent. For example, if recognition of something led to sending events to both a <play> and a <record> in that order, it is possible that the <record> may process its event before the <play>

Primitives each define the set of events which they support and the behavior associated with their handling of each event. This allow many types of behaviors to be defined. For example, VCR type controls

Saleem & Sharratt

can be constructed by defining primitives which support events corresponding to each control. Media recognition/detection can be used to cause those events to be generated.

Alternatively, events can be originated elsewhere, such as from an application server, and simply received by the primitive implementing the control. Examples of the use of events include adjusting volume (gain) and pause and resume of both announcement playout and record creation.

Primitives act on events based upon the longest match of an event name. Event names are a period '.' delimited sequence of tokens. The first token, or the root of the name, can be considered an event class. Matching allows a standard meaning to be defined and then extended based upon what triggers an event's generation. For example, a record primitive has different behavior depending upon whether it completed because a user stopped speaking or because it was cancelled. The recording is retained in the first case but not the second.

Longest match allows new recognizers to be created and used without changing how existing primitives are defined. For example, a face recognition capability could be created which generates a terminate.frowning event when a user looks puzzled. Although no primitive directly defines this event, it will still effect a generic terminate action. Primitives which require specialized behavior based upon frowning may be extended to support this. As well, the event can still be exported from the MOML context without requiring that primitives receiving the event understand facial expressions.

## Usage with SIP

MOML MAY be used directly with SIP for IVR or fax dialog interactions. It can be initially invoked as part of the "Prompt and Collect" service described in "Basic Network Media Services with SIP" [9]. That defines service indicators for a small number of well defined services using the user part of the SIP Request-URI (R-URI).

The prompt and collect service uses "dialog" as the service indicator. URI parameters further refine the specific IVR request. This document defines an additional parameter "moml-param" for the dialog service indicator as follows:

There are no additional URI parameters when MOML is used as the dialog language.

MOML defines discrete IVR dialog commands. These commands MAY be included directly in the body of the INVITE to the "dialog" service indicator by using the "cid" [12] URL scheme. This scheme identifies a message body part which in this case would contain the MOML command. Note that a multipart message body, containing a single part, MUST be present even if the INVITE does not contain an SDP offer. Subsequent MOML requests are sent in the body of SIP INFO messages as are all messages from a media server.

An example of SIP URI as described above is:

sip:dialog@mediaserver.example.net;\ moml=cid:14864099865376@appserver.example.net

The body part that contained the MOML referenced by the URL would have a Content-Id header of:

Content-Id: <14864099865376@appserver.example.net>

The results of executing an <exit> or <disconnect>, or of executing a <send> which has a "target" attribute value equal to "source", are notified in SIP INFO messages using the <event> element. No messages are sent if execution completes normally without executing one of these elements.

If there is an error during validation or execution, then a media server MUST notify the error as described above and must include the namelist items "moml.error.status" and "moml.error.description". The values for these items are defined in section 15.

A restricted subset of MOML can also be used with the "Announcement" service defined in [9]. This service uses "ann" as the service indicator and defines parameters that describe an announcement. The "play=" parameter identifies the URL of a prompt or a provisioned announcement sequence. The value of the "play=" parameter can refer to a MOML body part using a "cid" URL as described above. That body part must only contain the <play> primitive.

Using MOML enhances the announcement service by allowing the client to specify a sequence of audio segments rather than requiring each sequence to be provisioned. Moreover, MOML defines a standard set of variables in contrast to [9] which defines a parameterization mechanism but does not formally specify any semantics.

If a media server does not understand the "cid" scheme or does not understand MOML, it must respond with the SIP response code "488 -

Saleem & Sharratt

not acceptable here". If the MOML body contains elements other than the <play> primitive, or there are errors during validation, a media server must respond with a SIP response code "400 - bad request". Finally, if there is a discrepancy between parameters specified in the Request-URI and corresponding attributes defined in the MOML body, the Request-URI parameters must be silently ignored.

MOML MUST NOT change the operation of the announcement service from that defined in [9]. When the announcement completes, a media server issues a SIP BYE request. The INFO method MUST NOT used with the announcement service.

### 5. Package Scheme

The primary mechanism for extending MOML is the "package". A package is an integrated set of one or more XML schemas that define additional features and functions via new or extended use of elements and attributes. Each package is defined in a separate standards document, e.g., an Internet Draft or an RFC. All packages, extending the base MOML functionality, MUST include references to the MOML base set of schemas provided in the Internet drafts.

A schema in a package MUST extend MSML or MOML, i.e., may not mix MSML and MOML. A package MAY contain any combination of schemas extending MSML and schemas extending MOML.

A particular MSML or MOML script will include references to all the schemas defining the packages whose elements and attributes it makes use of. A particular script MUST reference either MSML base and optionally package(s) or MOML base and optionally package(s). See IANA Considerations section.

Each package MUST have its own namespace so that elements or attributes with the same name in different packages do not conflict. A script using a particular element or attribute MUST prefix the namespace name on that element or attribute's name if it is defined in a package (as opposed to being defined in the base).

## 6. Profile Scheme

Not all devices and applications using MSML/MOML will need to support the entire MSML/MOML base schema. For example, a media processing device might support only audio announcements, only audio simple conferencing, or only multimedia IVR. It is high desirable to have a system for describing what portion of the MSML/MOML base a particular media processing device or application server supports.

Since packages are the scheme used for describing chunks of MSML/MOML functionality beyond the MSML/MOML base, one possibility might be to

Internet-draft Media Objects Markup Language (MOML) October 2005

break the MSML/MOML base into a number of packages. MSML/MOML, however, is an XML-based language with sophisticated capabilities, and audio and video capabilities, for example, are intertwined in the schema. So it would not be technically feasible to break the MSML base and the MOML base into individual packages.

A better solution, and one more suited to the XML nature of MSML/MOML, is to create profiles of the MSML/MOML for the different uses. Each profile would identify a subset of the MOML/MOML base element and attributes, and each profile would be accompanied by one or two corresponding schemas that are a subset of the MSML base and/or the MOML base. To use the examples above, there could be an audio announcements profile, an audio simple conferencing profile, and a multimedia IVR profile.

These profiles would be published separately from the MSML/MOML base documents, in one or more standards documents (e.g., Internet Drafts or RFCs) dedicated to profiles. Public profiles would not be registered with IANA and any organization would be free to create its own private profile(s) if required.

# 7. Structure and Modularity

MOML is designed to be a modular language. Defining the language in terms of modules allows different vendors and communities to choose a specific language subset, or define different language extensions, for achieving a wide range of applications across a diverse set of platforms. Modularity combined with namespaces allow independent development of new extensions.

MOML is structured as a set of modules. Only a single module is required. That simple core module, moml-core-module, defines a MOML request to a media server. It consists of the primitive abstraction, an abstract element for control flow, the sequential execution model, and the <send> element. That is, the core module allows for the execution of a sequence of one or more media processing primitives with the ability to notify events to the invocation environment.

Primitives are divided into four modules. The first, moml-basicprimitives, defines the basic <play>, <record>, <dtmf>, and <vad> elements. Another module, moml-transform-primitives, defines the simple half duplex filters. More advanced primitives are defined in the speech and fax modules. The speech module depends on the play module as it extends the capability of <play> by adding synthesized speech. Finally, the group execution model, which is currently the only element which changes the flow of control is defined in a separate module. All of these module are optional although at least one primitive module is required to have a functional implementation.

Saleem & Sharratt

Internet-draft Media Objects Markup Language (MOML) October 2005

The formal process for defining extensions to MOML is to define a new module. The new module MUST provide a text description of what extensions are included and how they work. It MUST also define an XML schema file (if applicable) that defines the new module (which may be through extension or restriction of an existing module). Dependencies upon other modules MUST be stated. For example a module that extends or restricts has a dependency on the original. Finally, the new module MUST be assigned a unique name and version.

The types of things which can be defined in new modules are:

- o new primitives
- extensions to existing primitives (events, shadow variables, attributes, content)
- o new recognition grammars for existing primitives
- o new markup languages for speech generation
- o languages for specifying a topology schema
- o new pre-defined topology schemas
- o new variables / segment types (sets & languages)
- o new control flow elements

Modules are assembled together to form a specific MOML profile that is shared between different implementations. The base MOML profile which is defined in this documents consists of the moml-core, group, and basic and transform primitives modules. Speech and facsimile are examples of optional modules which extend the base language.

Modules which define primitives must define the following for each primitive within the module:

- o the function which the primitive performs
- o the attributes which may be used to tailor its behavior
- o the events which it is capable of understanding
- o the shadow variables which provide access to information determined as a result of the primitive's operation.

The mechanism used to insure that a media server and its client share a compatible set of modules is not defined. Currently it is expected that provisioning will be used, possibly coupled with a future auditing capability. Additionally, when used in SIP networks, modules could be defined using feature tags and the procedures defined for Indicating User Agent Capabilities in SIP [2] used to allow a media server to describe its capabilities to other user agents and its domain registrar.

#### 8. <moml>

The root element for MOML. The contents of this element describe either a complete execution context for a media resource object or the event to be notified to a MOML client.

Attributes:

version: "1.0" Mandatory.

id: an identifier unique to this object. Events returned from MOML (the "target" attribute of a <send> is equal to "source") will be correlated with this identifier. Mandatory.

Events:

terminate: terminates the MOML context. A terminate event gets sent to the currently executing <group> or primitive.

## 9. MOML Core Module

The core module defines the structural framework and abstractions for MOML (via its schema). It also defines the basic elements which are not part of the core primitive or control abstractions. These elements are defined below.

## 9.1 Elements Received by a Media Server

# 9.1.1 <send>

Sends an event and optional namelist to the recipient identified by the target attribute. Event names are defined by the recipient. In the case where the recipient is a MOML group or primitive, the events are defined within this document. Other recipients MAY use names that are suitable for their environment.

The "target" attribute specifies the recipient of the event. Recipients MAY be other MOML primitives or groups executing within the object, the object itself, or the environment which invoked MOML. Any target which is unknown within the object is assumed to be destined to the external environment. By convention, the string "source" SHOULD used to address that environment but any target name distinct from the MOML namespace MAY be used.

Saleem & Sharratt

#### Attributes:

event: the name of an event.

target: the recipient of the event. The recipient MUST be a MOML primitive, the currently executing group, or the MOML environment. A primitive is specified by a primitive type, optionally appended by a period '.' followed by the identifier of a primitive. Identifiers are only needed when more than one primitive of the same type exists in the object. The executing group is specified using the token "group". The environment is specified using the token "source", optionally appended by a period '.' followed by any environment specific target.

namelist: a list of zero or more shadow variables which are included with the event.

## 9.1.2 <exit>

Exit causes execution of the MOML object to terminate.

Attributes:

namelist: a list of one or more shadow variables which MAY optionally be sent to the context which invoked the MOML object.

#### 9.1.3 <disconnect>

Disconnect is similar to <exit> but has the additional semantics of indicating to the context which invoked the MOML object, that it should disconnect from a media server, the media stream associated with the object. The method of disconnection depends upon how the media stream was initially established. If SIP was used, a <disconnect> would cause a media server to issue a BYE request. The request would be sent for the SIP dialog associated with media session on which the MOML object was operating.

Attributes:

namelist: a list of one or more shadow variables which MAY optionally be sent to the context which invoked the MOML object.

## 9.2 Elements Sent by a Media Server

#### 9.2.1 <event>

The <event> element is used to describe an event and its associated namelist when MOML is used as a standalone dialog language such as with SIP. Events are generated and formatted when a <send>, <exit>, or <disconnect> is executed.

#### attributes:

name: the type of event. If the event is generated because of the execution of a <send>, the value MUST be the value of the "event" attribute from the <send> element. If the event is generated because of the execution of an <exit>, the value MUST be "moml.exit". If the event is generated because of the execution of a <disconnect>, the value MUST be "moml.disconnect". If the even is generated because of an error, the value must be "moml.error". Mandatory.

id: the identifier of the MOML object generating the event. Mandatory.

<event> has two children, <name> and <value>, which contain the name
and value respectively of each namelist item associated with the
event.

#### **10**. Group Module

The group module defines a single control flow construct that specifies concurrent execution. Future modules may define additional flow control constructs.

## <u>10.1</u> <group>

The <group> element allows the contained primitives to be executed concurrently.

Attributes:

topology: specifies a schema which defines the flow of media within the group. Three schemas are initially defined. "fullduplex" is specified for use with two dimensional groups. "parallel" and "serial" are for use with one dimensional groups. The definition of these topologies is defined in section 2. Mandatory.

id: identifies name of the group. Mandatory when groups are nested.

Events:

terminate: causes a terminate event to be sent to each element contained within the group.

## 10.2 <groupexit>

The <groupexit> element allows events to be sent when group processing completes. Group processing completes when all contained primitives terminate.

Attributes:

none

Events:

none

#### **11.** Basic Primitives Module

Subsections of a primitive define child elements of that primitive and are not themselves considered primitives. They do not receive events or populate shadow variables.

## **11.1** <play>

Play is used to generate an audio or video stream. It MUST play in sequence the media created by the child media elements <audio>, <video>, <media>, <tts>, and <var>. When the play stops, either because the terminate event is received or all media generation has completed, the <playexit> element, if present, is executed. At least one media generation element must be present.

Play supports two states; generate and suspend. Media generation occurs in the generate state and is suspended in the suspend state. Once in the suspend state, media generation continues upon receiving the generate event. The default initial state is generate.

Audio MAY be generated in different languages by specifying the xml:lang attribute for <play> and/or the child elements of <play>. The language is inherited by the child elements but each child MAY specify its own language. Except for physical audio clips, it is an error if a language is specified but the media server can not render the audio in the requested language.

Attributes:

Saleem & Sharratt Expires - April 2006

id: an optional identifier which may be referenced elsewhere for sending events to the play primitive.

interval: specifies the delay between stopping one iteration and beginning another. The attribute has no effect if iterations is not also specified. Default is no interval.

iterate: specifies the number of times the media specified by the child media elements should be played. Each iteration is a complete play of each of the child media elements in document order. Defaults to once '1'.

initial: defines the initial state for the play element. Default is "generate".

maxtime: defines the maximum allowed time for the <play> to complete.

barge: defines whether or not audio announcements MAY be interrupted by DTMF detection during play-out. The DTMF digit barging the announcement is stored in the digit buffer. Valid values for barge are true or false, and the attribute is mandatory.

cleardb: defines whether the digit buffer is cleared or not, prior to starting the announcement. Valid values for cleardb are true or false, and the attribute is mandatory.

offset: defines an offset, measured in units of time, where the <play> is to begin media generation. Offset is only valid when all child media elements are <audio>.

skip: an amount, expressed in time, which will be used to skip through the media when "forward" and "backward" events are received. Default is 3s (three seconds).

xml:lang: specifies the language to use for content which can be rendered in different languages.

# Events:

pause: causes the play to enter the suspend state.

resume: causes play to enter the generate state.

forward: skips forward through the media. Only has effect when all child media elements are <audio>.

backward: skips backward through the media. Only has effect when all child media elements are <audio>.

restart: skips to the beginning of the media. Only has effect when all child media elements are <audio>.

toggle-state: causes the suspend / generate state to toggle.

terminate: terminates the play and assigns values to the shadow variables.

Shadow Variables:

play.amt: identifies the length of time for which media was generated before the play was stopped. This does not include time which may have elapsed while the play was in the suspend state.

play.end: contains the event which caused the play to stop. When the play stops because all media generation has completed, end is assigned the value "play.complete".

Note: Attributes barge and cleardb provide a simplified mechanism for controlling play operations with implicit DTMF without the use of <group> and event exchange mechanism. When using the <play> element within the group framework and barge is specified, detection of barge condition generates an implicit terminate event to the play primitive.

#### **11.1.1 Child Elements**

## **11.1.1.1** <audio>

Identifies pre-recorded audio to play. Local URI references may resolve to a single physical audio clip, a logical clip, or a provisioned sequence of clips (physical or logical). A logical clip is one which can be rendered differently based on the language attribute. Logical clips are provisioned for each of the languages that a media server supports. Remote URI references are resolved according to the capabilities of the remote server.

Attributes:

uri: Identifies the location of the audio to be played. The file and http schemes are supported.

format: defines the encoding and file type of the audio
resource. The format attribute is defined as a string type of
form audio/<filetype>;codecs=<codec> . The keyword audio

Saleem & Sharratt

Expires - April 2006

[Page 22]

identifies an audio content. The codecs field identifies the audio file s codec to be used for decoding the audio content. If format attribute is not specified, the filetype MUST be determined from the URI and the codec information MUST be determined from the media resource.

audiosamplerate: Identifies audio sample rate in kHz. If not specified, the sample rate SHOULD be determined from the media resource.

audiosamplesize: Identifies audio sample size in bits. If not specified, the sample size SHOULD be determined from the media resource.

iterate: specifies the number of times the audio is to be played. Defaults to once '1'.

xml:lang: specifies the language to use when the URI identifies a logical clip, either directly, or as part of a sequence.

## **11.1.1.2** <video>

Identifies pre-recorded multimedia to play. Contents identified by the URI attribute may contain audio only, video only, or both audio and video. Media Server SHOULD attempt to play both audio and video from the identified URI, if both are available in the content.

Attributes:

uri: Identifies the location of the video or multimedia to be played. The file and http schemes are supported.

format: defines the encoding and file type of the video or multimedia resource. The format attribute is defined as a string type of form

video/<filetype>;codecs=<codecx>,<codecy> . The keyword video identifies video only media or media containing audio and video. The codecs field identifies the audio and/or video codecs to be used for decoding the file content, where the order of the codec values is not significant. In the event of audio and video content, using video keyword, the codecs=<codecx>,<codecy> field MAY be used to identify the audio codec and the video codec. If not specified, the codec information SHOULD be determined from the media file.

audiosamplerate: Identifies audio sample rate in kHz. If not specified, the sample rate SHOULD be determined from the media file.

audiosamplesize: Identifies audio sample size in bits. If not specified, the sample size SHOULD be determined from the media file.

codecconfig: Identifies an optional special instruction string for codec configuration. Default is to send no special configuration string to the codec.

profile: Identifies a video profile name specific to the codec. If not specified, default video profile of the codec SHOULD be selected.

level: Identifies a video profile level to the codec. Default is to send no profile information to the codec and allow the codec to select an internal default.

imagewidth: Identifies the width of video image in pixels. Default is to use image width information from media file.

imageheight: Identifies the height of video image in pixels. Default is to use image height information from media file.

maxbitrate: Identifies the bitrate of the video signal in kbps. Default is to use maximum bitrate information from the media file.

framerate: Identifies the video frame rate in frames per second. Default is to use frame rate information from the media file.

iterate: specifies the number of times the audio is to be played. Defaults to once '1'.

#### **11.1.1.3** <media>

Identifies multimedia content for play. All content of <media> element MUST start to play concurrently. This element may be used to generate a multi-media stream from two independent media resources, one identifying audio and the other identifying video.

The <media> element MUST contain at least one child element. Valid child elements of <media> are <audio> and <video>, as described earlier. <media> element MUST contain at most one <audio> element or at most one <video> element. Internet-draft Media Objects Markup Language (MOML) October 2005

## **11.1.1.4** <var>

Specifies the generation of audio from a variable using prerecorded audio segments. A variable represents a semantic concept (such as date or number) and dynamically produces the appropriate speech.

Prerecorded audio allows an application vendor or service provider to choose the exact voice for their audio and therefore completely control the "sound and feel" of the service provided to end users. It provides very high audio quality and allows the variables to blend seamlessly into the surrounding audio segments.

Text to speech (TTS) using SSML may also be used to render variables, but may not provide as good quality, or allow as complete control of the "sound and feel" or user experience. TTS is normally used for reading text such as emails and for very large vocabularies such as stock names. TTS results in a very clear difference between the variables and the surrounding audio segments.

Attributes:

type: specifies the type of variable. Mandatory. Variable type must be one of "date", "digits", "duration", "month", "money", "number", "silence", "time", or "weekday".

subtype: specifies an optional clarification of type. Specific values depend upon the type.

value: text which should be rendered appropriate to the type and subtype attributes.

xml:lang: specifies the language to use when rendering the variable.

# **11.1.1.5** <playexit>

The <playexit> element MUST be invoked when generation of all content of the <play> has come to completion. The contents of this element MAY be used to send events.

Attributes:

none

### 11.2 <dtmfgen>

DTMF generator originates one or more DTMF digits in sequence.

Attributes:

id: an optional identifier which may be referenced elsewhere for sending events to the dtmfgen primitive.

digits: A string of characters from the alphabet "0-9a-d#\*" which correspond to a sequence of DTMF tones. Mandatory.

level: used to define the power level for which the tones will be generated. Expressed in dBmO in a range of O to -96 dBmO. Larger negative values express lower power levels. Note that values lower than -55 dBmO will be rejected by most receivers (TR-TSY-000181, ITU-T Q.24A). Default is -6 dBmO.

dur: the duration in milliseconds for which each tone should be generated. Implementations may round the value if they only support discrete durations. Default 100 ms.

interval: the duration in milliseconds of a silence interval following each generated tone. Implementations may round the value if they only support discrete durations. Default 100 ms.

Events:

terminate: terminates DTMF generation and assigns values to the shadow variables.

Shadow Variables:

dtmfgen.end: contains the event which caused DTMF generation to stop.

# **11.2.1** Child Elements

## 11.2.1.1 <dtmfgenexit>

The <dtmfgenexit> element MUST be invoked when the DTMF generation operation completes or is terminated as a result of receiving the terminate event. The <dtmfgenexit> element MAY be used to send events when the recording has completed.

Attributes:

none

#### 11.3 <record>

Record creates a recording. Similar to play, <record> supports two states; create and suspend. Received media becomes part of the recording when <record> is in the create state and is discarded when it is in the suspend state.

Saleem & Sharratt Expires

Recording MUST be terminated when a terminate event is received or when a nospeech event is received and no audio has yet been recorded. <record> differentiates different types of terminate events.

An optional <play> element MAY be specified as a child element of <record>. This mechanism provides a complete play-record operation, where the prompt(s) specified within the <play> element are played in advance of start of recording.

Note: Attributes prespeech, postspeech, and termkey provide a simplified mechanism for controlling record operations using implicit DTMF and VAD, without the use of <group> and event exchange mechanism.

Attributes:

id: an optional identifier which may be referenced elsewhere for sending events to the record primitive.

append: a boolean which defines whether the recording is allowed to be appended to an existing file if dest already exists. Default is "false". The attribute is ignored if the scheme is http.

dest: the destination for the recording, which will contain either audio only, video only, or both audio and video depending on the stream(s) being recorded. Recording MAY be either local or external based upon the attribute value. File and http schemes are supported.

audiodest: the destination for the audio only recording. Recording MAY be either local or external based upon the attribute value. All combinations of dest, audiodest, and videodest are valid. File and http schemes are supported.

videodest: the destination for the video only recording. Recording MAY be either local or external based upon the attribute value. All combinations of dest, audiodest, and videodest are valid. File and http schemes are supported.

format: defines the encoding and file type of the recording. The format attribute is defined as a string type of form audio|video/filetype;codecs=x,y . The keyword audio identifies an audio only recording, while the keyword video identifies video only recording or an audio plus video recording. The codecs field identifies the audio and/or video codecs to be used for the recording, where the order of the codec values is not significant. In the event of audio and

Saleem & Sharratt Expires - April 2006

video recording, using video keyword, the codecs=x,y field MAY be used to identify the audio codec and the video codec.

codecconfig: Identifies an optional special instruction string for codec configuration. Default is to send no special configuration string to the codec.

audiosamplerate: Identifies audio sample rate in kHz. If not specified, the sample rate SHOULD be determined from the media source.

audiosamplesize: Identifies audio sample size in bits. If not specified, the sample size SHOULD be determined from the media source.

profile: Identifies a video profile name specific to the codec. If not specified, default video profile of the codec SHOULD be selected for the recording.

level: Identifies a video profile level to the codec. Default is to send no profile information to the codec and allow the codec to select an internal default.

imagewidth: Identifies the width of video image in pixels. Default is to use image width information from the media source.

imageheight: Identifies the height of video image in pixels. Default is to use image height information from the media source.

maxbitrate: Identifies the bitrate of the video signal in kbps. Default is to use maximum bitrate information from the media source.

framerate: Identifies the video frame rate in frames per second. Default is to use frame rate information from the media source.

initial: defines the initial state for the record element. Default is "create", which starts the recording as soon as the <record> element is executed. The initial attribute is applicable only when <record> is used within the <group> structure.

maxtime: defines the maximum length of the recording in units of time.

prespeech: defines a timer value, in seconds, for detection of absence of audio energy at the start of the record operation. If no audio energy is detection for the amount of time specified by prespeech, the recording is terminated. Default is 0s , which does not activate the prespeech timer.

postspeech: defines a timer value, in seconds, for detection of absence of audio energy while the recoding is in progress. During an in progress recording, if absence of audio energy is detected as specified by the postspeech timer, the recording is terminated. Default is Os , which disables the ability to terminate a recording due to postspeech silence.

termkey: defines a single DTMF key which when detection terminates the recording. Absence of this attribute prevents the recording from being terminated due to detection of DTMF digits. When termkey is specified, the detected DTMF digit terminates the recording and the DTMF digit is not entered in the digit buffer.

Events:

Following describes input events to the media primitive object. The Group Model allows an event exchange mechanism between primitives.

pause: causes the record to enter the suspend state. Received media is discarded.

resume: causes record to resume if it was suspended. It has no effect otherwise.

toggle-state: causes the suspend / create state to toggle.

terminate: terminates the recording and assigns values to the shadow variables.

terminate.cancelled: terminates the recording and assigns values to the shadow variables. If the dest attribute used the file scheme, the local recording is deleted. Applications are responsible for removing external files created using the http scheme.

terminate.finalsilence: terminates the recording and assigns values to the shadow variables. If the dest attribute used the file scheme, the final silence is removed from the recording.

nospeech: terminates the recording and assigns values to the shadow variables if it is received and no recording has yet

been created. The "nospeech" event is ignored if audio has already been recorded.

Shadow Variables:

record.len: the actual length of the recording measured in units of time. This does not include time which may have elapsed while the record was in the suspend state.

record.end: contains the event which caused the record to terminate. When the record terminates because maxtime is exceeded, end is assigned the value "record.complete.maxlength".

Record termination due to prespeech silence, results in assigned value of record.failed.prespeech

Record termination due to postspeech silence, results in assigned value of record.complete.postspeech

Record termination due to DTMF detection, results in assigned value of record.complete.termkey

## **11.3.1** Child Elements

## **11.3.1.1** <play>

The optional <play> element as a child element of <record> allows a prompt to be played prior to start of recording. The record operation starts at the end of the play sequence or if the play is barged by DTMF, assuming that barge=true is specified for <play>. For a complete description, refer to <play> element.

#### 11.3.1.2 <recordexit>

The <recordexit> element MUST be invoked when the record operation completes or when the recording is terminated as a result of receiving the terminate event. The <recordexit> element MAY be used to send events when the recording has completed.

Attributes:

none

### 11.4 <dtmf> or <collect>

DTMF input fulfils several roles within MOML. It is used to trigger events which will affect the media processing operation of other primitives. It is also used to collect DTMF digits from a media

Saleem & Sharratt

Internet-draft Media Objects Markup Language (MOML) October 2005

stream which are to be reported back to the user of MOML. Often DTMF detection is used for both purposes. Barge is the most common example, where a prompt is stopped based upon DTMF input but more digits may remain to be collected.

DTMF detection supports multiple simultaneous recognition patterns. Different patterns can be used to trigger sending different events in order to implement DTMF controls. Alternatively one pattern may be used to represent a collection and another pattern, a substring of the first, used as a barge indication.

An optional <play> element MAY be specified as a child element of <dtmf> or <collect>. This mechanism provides a complete play-collect operation, where the prompt(s) specified within the <play> element are played in advance of DTMF digit collection.

Note that all patterns share the same digit collection buffer, interdigit timing, a single <nomatch> element, and a single <noinput> element. As such, multiple patterns may not be suitable to support simultaneous collections for different purposes. When this is required, separate <dtmf> elements should be used instead.

<dtmf> terminates if any of the <pattern>, <noinput>, or <nomatch>
elements are matched the maximum number of times that they are
allowed. The number of times they may match may be specified as an
attribute of <dtmf> or of the individual child elements.

Element identifier <dtmf> is equivalent to <collect>. However, <collect> is the preferred name. MOML clients should use <collect>, while MOML servers should support both.

Attributes:

id: an optional identifier which may be referenced elsewhere for sending events to this primitive.

cleardb: a boolean indication of whether the buffer for digit collection should be cleared of any collected digits when the element is instantiated. If set to false, any digits currently in the buffer MUST be immediately compared against the pattern elements.

fdt: defines the first-digit timer value. The first-digit timer is started when DTMF detection is initially invoked. If no DTMF digits are detected during this initial interval, the <noinput> element MUST be invoked.

idt: defines the inter-digit timer to be used when digits are being collected. When specified, the timers is started when the

first digit is detected and restarted on each subsequent digit. Timer expiration is applied to all patterns. After that, if any patterns remain active and a nomatch element is specified, the nomatch is executed and DTMF input MUST terminate. The idt attribute should only be used when digit collection is being performed. No default.

starttimer: boolean value which defines whether the first digit timer (fdt) is started initially. When set to false, the starttimer event must be received for it to start. Default false.

iterate: specifies the number of times the <pattern>, <noinput>, and <nomatch> elements may be executed unless those elements specify differently. The value "forever" MAY be used to indicate that these may be executed any number of times. Default is once '1'.

## Events:

Following describes input events to the media primitive object. The Group Model allows an event exchange mechanism between primitives.

starttimer: starts the first digit timer (fdt) if it has not already been started. Has no effect otherwise.

terminate: terminates the DTMF input and assigns values to the shadow variables.

Shadow Variables:

dtmf.digits: the string of DTMF digits which have been received (the contents of the digit buffer).

dtmf.len: the number of digits in the digit buffer.

dtmf.last: the last digit in the digit buffer.

dtmf.end: contains the event which caused the <dtmf> to terminate or is assigned one of "dtmf.match", "dtmf.noinput", or "dtmf.nomatch" depending upon which of the corresponding elements reached its maximum. Internet-draft Media Objects Markup Language (MOML) October 2005

## **11.4.1** Child Elements

### **11.4.1.1** <play>

The optional <play> element as a child element of <dtmf> or <collect> allows a prompt to be played prior to DTMF digit collection. DTMF digit collection starts at the end of the play sequence or if the play is barged by DTMF, assuming that barge=true is specified for <play>. For a complete description, refer to <play> element.

### **11.4.1.2** <pattern>

The pattern element describes one or more DTMF digits that are to be recognized. When the pattern is matched, the child elements MUST be executed.

Attributes:

digits: The digit pattern which should be matched.

format: an enumerated value which defines the format used to express the digit pattern. The format may be "mgcp" or "megaco" for patterns expressed as digit map from those specifications, or as one of the simple built-in formats defined within this specification. Currently, a single built-in format "moml+digits" is defined which allows a match based on either one or more specific digits, or based upon a specific length specification with an optional return key. "moml+digits" is the default.

iterate: specifies the number of times the <pattern> may be matched. The value "forever" may be used to indicate that <pattern> may be matched any number of times. This value overrides any specified in <dtmf>. Default is once '1'.

#### **11.4.1.3** <detect>

The contents of the <detect> element MUST be executed whenever any DTMF is first detected. It MUST be matched at most once.

Attributes:

none

## **11.4.1.4** <noinput>

The <noinput> element is used when DTMF is being collected. Children of the <noinput> element MUST be executed when DTMF has not been detected and the first digit timeout occurs.

Saleem & Sharratt

Attributes:

iterate: specifies the number of times the <noinput> may be triggered. The value "forever" may be used to indicate that <noinput> may be triggered any number of times. This value overrides any specified in <dtmf>. Default is once '1'.

## **11.4.1.5** <nomatch>

The <nomatch> element is used when DTMF is being collected. Children of the <nomatch> element MUST be executed when it is determined that none of the individual patterns can be matched.

#### Attributes:

iterate: specifies the number of times the <nomatch> may be triggered. The value "forever" may be used to indicate that <nomatch> may be triggered any number of times. This value overrides any specified in <dtmf>. Default is once '1'.

#### **11.4.1.6** <dtmfexit>

The <dtmfexit> element MUST be invoked when the dtmf input completes because one of <pattern>, <noinput>, or <nomatch> occurred its maximum number of times.

Attributes:

none

#### **12**. Transform Primitives Module

The transform primitives module gathers together the simple primitives which work as filters on half duplex media streams.

#### **12.1** <vad>

Voice activity detection (VAD) is used to detect voice and silence when speech recognition is not required. Similar to both speech and DTMF, a VAD has different media conditions which it can match. Those conditions can be qualified by a minimum length of time which is required for them to be considered recognized.

Attributes:

starttimer: boolean value which defines whether the timer is started to allow recognition of the initial condition (voice,

Saleem & Sharratt

silence). When set to false, the starttimer event must be received in order for the initial condition to be recognized. The timer does not affect recognition of the transition conditions. Default false.

### Events:

starttimer: starts the timer to allow recognition of the initial condition if it has not already been started. Has no effect otherwise.

terminate: terminates voice activity detection.

Shadow Variables:

none

## 12.1.1 Child Elements

#### 12.1.1.1 <voice>, <silence>, <tvoice>, <tsilence>

Each child element corresponds to a condition which a VAD can detect. The first two detect when voice or silence has been initially present for a minimum length of time since the VAD was started. The second two require that a transition to the voice or silence condition first occur.

Attributes:

len: the length of time the condition must persist in order to be recognized. In the case of <tvoice> and <tsilence>, the length of time applies only to the final recognized condition.

sen: the maximum length of time the condition not being detected may occur without causing the detector to begin measuring that condition.

#### **12.2** <gain>

Gain MAY be used to adjust of the gain of a media stream by a specific amount.

attributes:

incr: an increment, expressed in dB, which will be used to adjust the gain when "louder" and "softer" events are received. Default is 3 dB.

amt: a specific gain to apply specified in dB.

Saleem & Sharratt

mute: self explanatory. unmute: self explanatory. reset: sets the gain to zero dB. louder: makes the audio on a stream louder. softer: makes the audio on a stream quieter. amt: sets the gain to the specified value between -96 dB and 9 dB.

## **12.3** <agc>

Automatic gain control MAY be used to have a media server automatically adjust the gain of a media stream.

attributes:

events:

tgtlvl: the desired target level for AGC specified in dBm0.

maxgain: the maximum gain that AGC will apply specified in dB.

events:

mute: self explanatory.
unmute: self explanatory.

#### **12.4** <gate>

A simple filter which will pass or halt media, regardless of the format of the media stream, based on the events it receives. <gate> shares the same mute and unmute events for compatibility with the gain primitives <gain> and <agc>.

attributes:

initial: the values "pass" and "halt" define whether media is initially allowed to pass. Default is to pass.

events:

mute: halts media flow through the primitive.

unmute: allows media to pass through the primitive.

Saleem & Sharratt Expires - April 2006
Internet-draft Media Objects Markup Language (MOML) October 2005

#### **12.5** <clamp>

This element MAY be used to filter DTMF tones from a media stream. Media other than DTMF tones is passed unchanged.

attributes:

none.

events:

none.

# **12.6** <relay>

This element is a simple primitive which copies its input to its output.

attributes:

none.

events:

none.

## **13**. Speech Module

The speech module defines a standalone primitive which MAY be used for automatic speech recognition <speech> and extends the <play> primitive defined in the basic primitives module to include speech synthesis. As such, this module depends on the basic primitives module.

# 13.1 <speech>

Activates grammars or user input rules associated with speech recognition. If multiple grammars are specified, all are activated. All active grammars share the same timers, recognition attributes, and <noinput> and <nomatch> elements. Each grammar may have its own <match> element.

<speech> terminates if any of the <grammar>, <noinput>, or <nomatch> elements are matched the maximum number of times that they are allowed. The number of times they may match may be specified as an attribute of <speech> or of the individual child elements.

Attributes:

noint: specifies a time period during which speech input must be started, otherwise the associated <noinput> element is invoked.

norect: specifies a maximum time period during in which speech must begin to be matched, otherwise the associated <nomatch> element is invoked.

spcmplt: specifies the length of silence necessary after speech before a result will be finalized in the case where there is a complete match of an active grammar. Following the silence, the appropriate <match> element will be triggered if the result is above the confidence level. Otherwise a <nomatch> element will be triggered.

spincmplt: specifies the length of silence necessary after speech before a result will be finalized in the case where there is a incomplete match of all active grammars. Following the silence, the <nomatch> element will be triggered.

confidence: the minimum confidence level which the recognizer must have to consider a recognition result as matching a grammar. Expressed as an integer between 1-100.

sens: specifies the sensitivity of the recognizer to determine whether speech is present. Lower sensitivity may be required for the recognizer to work well in the presence of high background noise or line echo.

starttimer: boolean value which defines whether the no input (noint) and no recognition (norect) are started initially. When set to false, the starttimer event must be received in order to start them. Default false.

iterate: specifies the number of times the <grammar>, <noinput>, and <nomatch> elements may be executed unless those elements specify differently. The value "forever" may be used to indicate that these may be executed any number of times. Default is once '1'.

## Events:

sens: sets the sensitivity of the recognizer as described above.

starttimer: starts the no input (noint) and no recognition (norect) timers if they have not already been started. Has no effect otherwise.

terminate: terminates the speech input and assigns values to the shadow variables.

Shadow Variables:

speech.end: contains the event which caused the <speech> to terminate or is assigned one of "speech.match", "speech.noinput", or "speech.nomatch" depending upon which of the corresponding elements reached its maximum.

speech.results: contains the results of a matched grammar. The results are formatted using the Natural Language Semantics Markup Language (NLSML) [6]. When this variable is referenced to return results, the results are returned as a separate MIME entitv.

#### **13.1.1** Child Elements

#### **13.1.1.1** <grammar>

Specifies and activates a speech grammar based on Speech Recognition Grammar Specification (SRGS) [5] XML notation. Grammars may be referenced by a URI or defined inline. Child elements of <match> MUST be executed when the specified speech grammar is matched.

Attributes:

uri: specifies the location of an SRGS grammar when the grammar is not defined inline.

iterate: specifies the number of times the <grammar> may be matched. The value "forever" MAY be used to indicate that <grammar> may be matched any number of times. This value overrides any specified in <speech>. Default is once '1'.

#### **13.1.1.2** <match>

<match> is a child of <grammar> and specifies the actions to take when the corresponding grammar is matched.

### **13.1.1.3** <noinput>

The <noinput> element is used when speech is being recognized. Children of the <noinput> element MUST be executed when speech has not been detected and the no input timeout (noint) occurs.

Attributes:

Saleem & Sharratt Expires - April 2006

iterate: specifies the number of times the <noinput> may be triggered. The value "forever" may be used to indicate that <noinput> may be triggered any number of times. This value overrides any specified in <speech>. Default is once '1'.

#### **13.1.1.4** <nomatch>

The <nomatch> element is used when speech is being recognized. Children of the <nomatch> element MUST be executed when it is determined that none of the active grammars will match.

### Attributes:

iterate: specifies the maximum number of times the <nomatch> may be triggered. The value "forever" MAY be used to indicate that <nomatch> may be triggered any number of times. This value overrides any specified in <speech>. Default is once '1'.

## 13.1.1.5 <speechexit>

The <speechexit> element MUST be invoked when the speech input completes because one of <grammar>, <noinput>, or <nomatch> occurred its maximum number of times.

Attributes:

none

## <u>13.2</u> <play>

The <play> element, as defined in the basic primitives module, is extended with a new child element for synthesizing speech. From an XML perspective, <tts> is a member of a media substitution group. See the schema at the end of this document for details.

#### **13.2.1** Child Elements

### 13.2.1.1 <tts>

Contents of the <tts> element are rendered using Text To Speech services and must be compliant to the SSML specification. Element content MAY be plain text, contain the SSML <speak> element, or the uri attribute should identify the location of text to be rendered.

Attributes:

uri: Identifies the location of the text to be rendered. The file and http schemes are supported.

Saleem & Sharratt

Expires - April 2006

iterate: specifies the number of times the text to speech block is to be rendered. Defaults to once '1'.

xml:lang: specifies the language to use when it is not explicitly specified as an attribute for <speak>.

### **14**. Fax Module

The fax module defines primitives which allow a media server to provide facsimile services.

### 14.1 <faxdetect>

Fax tone detection is used to detect the presence of the T.30 CNG tone in a media stream. Child elements of <faxtone> are executed when the CNG tone is detected.

Attributes:

none

#### 14.2 <faxsend>

The <faxsend> primitive provides the functionality of a calling fax terminal. This typically means sending a set of pages. However, it can also mean requesting the called terminal to send pages instead of, or in addition to, sending pages. The fax images to send are defined by the <sendobj> elements, described below.

Requesting the called terminal to send pages happens when the <rxpoll> element is included as part of <faxsend>. This element may be included in addition to, or instead of, the <sendobj> element. One <sendobj> (at a minimum) or <rxpoll> element must be present. When both are present, a media server will first send pages and will then poll the other terminal, requesting pages.

Because fax is a distinct media type, the <faxsend> primitive is not expected to interact with other primitives. Rather, it will interact using fax protocols with a remote fax terminal (or gateway) and will send requested status events to its invoking environment. During fax operation, shadow variables are used to record the progress and parameters of the varying stages of fax operation.

Status events are requested by including one or more status request elements. These elements correspond to different stages or events in fax operation and cause pre-defined events to be sent to the invoking environment when they occur. Since the only recipient of these events

Saleem & Sharratt

Expires - April 2006

is expected to be a fax application server, requests are simplified by associating a pre-defined namelist of shadow variables with each event. This decision may be revisited to allowed tailored namelists based on further implementation experience. Status requests apply both to sending and polling operation.

Attributes:

lclid: the identifier that a media server uses to identify itself.

minspeed: the minimum acceptable speed to negotiate for the operation.

maxspeed: the maximum speed to negotiate for the operation. This attribute is primarily for testing purposes.

ecm: specifies whether Error Correction Mode (ECM) is allowed to be used if supported by the remote terminal. Defaults to "true".

Events:

terminate: terminates the fax send operation.

Shadow Variables:

fax.rmtid: the identifier of the remote fax terminal.

fax.rate: the negotiated speed for the operation.

fax.resolution: identifies the resolution of the image. Both
metric and inch based resolutions are defined. Metric based
resolutions are: 75x75, 150x150, 204x98, 204x196, 204x391,
408x391. Inch based resolutions are: 200x200, 300x300, 400x400,
600x600.

fax.pagesize: identifies the negotiated page size. Metric sizes are "A3", "A4", "A5", "A6", and "B4". Inch based page sizes are "Letter" and "Legal".

fax.encoding: identifies the image encoding utilized. Valid values are "MH", "R", "MMR", and "JPEG".

fax.ecm: identifies whether ECM operation was used.

fax.pagebadlines: the number of bad lines in a page.

fax.objbadlines: the number of bad lines in an object.

fax.opbadlines: the number of bad lines in an operation.

fax.objuri: the objuri of the current object.

fax.resendcount: the number of pages resent due to errors.

fax.totalpages: the number of pages processed or stored.

fax.totalobjects: the count of the objects used in the operation.

fax.duration: the duration of the operation expressed as a duration in seconds and milliseconds (e.g. "23s250ms").

fax.result: contains the reason which caused the fax operation to complete. When the operation completes successfully, the value will be assigned "fax.success". Other values include: "fax.partial", "fax.nofax", "fax.remotedisconnect", "fax.uri.access.error", and "fax.invalid.startpage".

### 14.2.1 Child Elements

#### **14.2.1.1** <sendobj>

<sendobj> is used to define a fax transmission. There MAY be multiple
instances of the element which will be transmitted in order.

Attributes:

objuri: a URI that points to the fax image that will be transmitted. Mandatory.

startpage: the first page of a multi-page objuri to send.

pagecount: page count.

### 14.2.1.2 <hdrfooter>

<hdrfooter> describes the header/footer that a media server MAY put
on pages. The header or footer may be defined as the content of the
<format> child element. The <format> element is only allowed if the
type attribute has a value of "header" or "footer".

Attributes:

type: specifies whether a header or a footer should be put on pages and identifies the source of the header or footer. The following enumerated values may be used:

Saleem & Sharratt

Expires - April 2006

- "header" indicates that the media server should put a header on pages using the contents of the <format> element.
- "nohdr" indicates that there should be no header or footer.
- "footer" indicates that the media server should put a footer on pages using the contents of the <format> element.

style: defines the style of insertion onto a fax page that a media server should use for the header or footer. Valid styles are "append", "overlay", or "replace".

<format> is a child of the <hdrfooter> element that defines the style format to be used for the header or footer. It uses a "C" language style format statement (as shown below) to define the contents and layout of the header or footer.

code	length	name	format
%a	3	day of week	3-character abbreviation
%d	2	date	01-31
%m	2	month	01-12
%у	2	year	00-99
%Y	4	year	0000-9999
%I	2	12 hour	01-12
%H	2	24 hour	00-23
%M	2	minute	00-59
%S	2	seconds	00-59
%р	2	AM/PM	AM or PM
%P	2	page number	01-99
%Т	2	total pages	01-99
%1	20	local ID (sender)	0-9, + or spaces
%r	20	remote ID (rcvr)	0-9, + or spaces
%%	1	percent	display % in header/ftr

### **14.2.1.3** <rxpoll>

<rxpoll> provides the information necessary for a receive polling operation to occur. The object(s) to be received are defined by one or more <rcvobj> elements. The <rcvobj> is defined further under the child elements of <faxrcv>. The <rxpoll> element MAY also include a description of the header/footer that a media server SHOULD put on received pages. The <hdrfooter> element and it's usage is described above.

Attributes:

rmtid: specifies the identifier of the remote fax terminal that to be associated with a polling operation. A media server MUST NOT execute a polling operation unless the value of rmtid matches that of the connected remote machine.

### **14.2.1.4** <faxstart>

Requests that an event be sent when fax operation has begun. When triggered, the following will be executed:

```
<send target="source" event="fax.start"/>
```

## 14.2.1.5 <faxnegotiate>

Requests that an event be sent when a negotiation has been completed. Multiple events MAY be sent each time a DCS frame is sent or received. When triggered, the following will be executed:

```
<send target="source" event="fax.negotiate"
namelist="fax.rmtid
fax.rate
fax.resolution
fax.pagesize
fax.encoding
fax.ecm"/>
```

## 14.2.1.6 <faxpagedone>

Requests that an event be sent when a page has been sent or received. When triggered, the following will be executed:

<send target="source" event="fax.pagedone"
 namelist="fax.resolution
 fax.pagesize
 fax.encoding
 fax.pagebadlines
 fax.resendcount"/>

### 14.2.1.7 <faxobjectdone>

Requests that an event be sent when an objuri has been completed. When triggered, the following will be executed:

```
<send target="source" event="fax.objectdone"
    namelist="fax.objuri
    fax.objbadlines
    fax.resendcount
    fax.totalpages
    fax.result"/>
```

#### 14.2.1.8 <faxopcomplete>

Requests that an event be sent when an operation has been completed. When triggered, the following will be executed:

<send target="source" event="fax.opcomplete"
 namelist="fax.totalpages
 fax.opbadlines
 fax.resendcount
 fax.totalobjects
 fax.duration
 fax.result"/>

#### 14.2.1.9 <faxpollstarted>

Requests that an event be sent when a polling operation has started. When triggered, the following will be executed:

<send target="source" event="fax.opcomplete"
 namelist="fax.rmtid
 fax.rate
 fax.resolution
 fax.pagesize
 fax.encoding
 fax.ecm"/>

### 14.3 <faxrcv>

The <faxrcv> primitive provides the functionality of a called fax terminal. Typically this type of operation is to receive pages. However, it can include sending pages instead of, or in addition to, receiving them. The fax objects to receive are defined by the <rcvobj> elements, described below.

A media server SHOULD send pages as a polled terminal when the <txpoll> element is included as part of <faxrcv>. This element may be included in addition to, or instead of, the <rcvobj> element. One <rcvobj> or <txpoll> element must be present. When both are present, a media server SHOULD first receive pages and will then allow the other terminal to poll the media server, requesting pages.

Because fax is a distinct media type, the <faxrcv> primitive is not expected to interact with other primitives. Rather, it will interact using fax protocols with a remote fax terminal and will send requested status events to its invoking environment. During fax operation, shadow variables are used to record the progress and parameters of the varying stages of fax operation.

Saleem & Sharratt Expires - April 2006

Internet-draft Media Objects Markup Language (MOML) October 2005

Status events are requested by including one or more status request elements. These elements correspond to different stages or events in fax operation and cause pre-defined events to be sent to the invoking environment when they occur. Since the only recipient of these events is expected to be a fax application server, requests are simplified by associating a pre-defined namelist of shadow variables with each event. This decision may be revisited to allowed tailored namelists based on further implementation experience. Status requests apply both to receiving and polling operation.

Attributes:

lclid: the identifier that a media server uses to identify itself.

ecm: specifies whether ECM mode is allowed to be used if supported by the remote terminal. Defaults to "true".

Events:

terminate: terminates the fax reception operation.

Shadow Variables:

<faxrcv> supports the same set of shadow variables as <faxsend>

## **14.3.1** Child Elements

In addition to the elements defined below, <faxrcv> MAY also have the following child elements which were defined under <faxsend>:

- o <hdrfooter>
- o <faxstart>
- o <faxnegotiate>
- o <faxpagedone>
- o <faxobjectdone>
- o <faxopcomplete>
- o <faxpollstarted>

Their meaning and usage is the same as previously defined.

## **14.3.1.1** <rcvobj>

<rcvobj> is used to define fax objects that a media server will receive. There may be multiple instances of the element which will be used in order.

Attributes:

objuri: a URI that points to the location that a received image is to be stored. Mandatory.

maxpages: the maximum number of pages that will be stored in objuri.

### 14.3.1.2 <txpoll>

<txpoll> provides the information for a polling operation to occur as part of a fax receive operation. Multiple object(s) to be send may be supplied by one or more <sendobj> elements. In the event of multiple occurrences, a media server MUST select the <sendobj> element whose rmtid attribute matches that of the remote terminal.

The <sendobj> element was defined previously as a child element of <faxsend>. For <txpoll> is extended with an rmtid attribute that specifies the identifier of the remote fax terminal and is used to select the specific <sendobj> to send.

A media server SHOULD put a header/footer on transmitted pages based on any <hdrfooter> element included as part of <txpoll>.

Attributes:

none

# **15**. Failure Codes

Failure codes are used to indicate reasons for failures. The appropriate code and description must be passed to the invoking environment on failure.

Request Error (4xx)

- 400 Bad Request 401 Unknown Element
- 402 Unsupported Element
- 403 Missing mandatory element content
- 404 Forbidden element content
- 405 Invalid element content

```

### **16**. Examples

#### **16.1** Announcement

The following is a simple announcement scenario. Two recorded audio files are played in sequence followed by generated speech followed by a variable. The results are reported once media generation completes.

```
<?xml version="1.0" encoding="UTF-8"?>
<moml version="1.0" id="12345">
  <play>
      <audio uri="file://clip1.wav"/>
      <audio uri="http://host1/clip2.wav"/>
      <tts uri="http://host2/text.ssml"/>
      <var type="date" subtype="mdy" value="20030601"/>
  </play>
  <send target="source" event="done" namelist="play.amt play.end"/>
</moml>
```

#### **16.2** Voice Mail Retrieval

Below is an example which shows a simple voice mail retrieval operation consisting of playing a message and allowing the user to pause and resume play using '5' to toggle the state. The operation would terminate when the play completed or the user entered '#'. During the play, the user can advance forward and backward through the message as well as rewinding to the beginning.

```
<?xml version="1.0" encoding="UTF-8"?>
<moml version="1.0" id="12345">
   <group topology="parallel">
      <play>
         <audio uri="file://message.wav"/>
         <playexit>
            <send target="group" event="terminate"/>
         </playexit>
      </play>
      <dtmf iterate="forever">
         <pattern digits="5">
            <send target="play" event="toggle-state"/>
         </pattern>
         <pattern digits="6">
            <send target="play" event="forward"/>
         </pattern>
```

```
<pattern digits="7">
            <send target="play" event="backward"/>
         </pattern>
         <pattern digits="8">
            <send target="play" event="restart"/>
         </pattern>
         <pattern digits="#">
            <send target="play" event="terminate"/>
         </pattern>
      </dtmf>
   </group>
</moml>
```

### 16.3 Play and Record

A more complex example is a play and record operation. This sources and sinks media and uses voice activity DTMF detection and recognition to influence behavior. Any DTMF input or voice activity will barge the play and cause the record to begin. However, if the prompt was barged with a DTMF digit of '#', the record terminates without starting. When the play terminates, it send a starttimer event to the VAD to allow it to recognize an initial silence condition. The recording will be terminated (without starting) when the VAD detects an initial 3 seconds of silence.

Once resumed (based upon voice detection) the recording may be terminated under several conditions. It will terminate after 5 seconds of silence or after 60 seconds elapses. It will also terminate if a '#' key is recognized. Every aspect of this behavior can be modified by changing what is recognized and the events which are sent.

```
<?xml version="1.0" encoding="UTF-8"?>
<moml version="1.0" id="12345">
   <group topology="parallel">
      <play>
         <audio uri="file://prompt.wav"/>
         <playexit>
            <send target="vad" event="starttimer"/>
         </playexit>
      </play>
      <dtmf>
         <pattern digits="#">
            <send target="record" event="terminate.termkey"/>
         </pattern>
         <detect>
            <send target="play" event="terminate"/>
         </detect>
      </dtmf>
```

[Page 51]

```
<vad>
         <voice len="10ms">
            <send target="play" event="terminate"/>
            <send target="record" event="resume"/>
         </voice>
         <silence len="3s">
            <send target="record" event="nospeech"/>
         </silence>
         <tsilence len="5s">
            <send target="record" event="terminate.finalsilence"/>
         </tsilence>
      </vad>
      <record initial="suspend" maxtime="60s"
              dest="file://record.wav" format="g729">
         <recordexit>
            <send target="group" event="terminate"/>
         </recordexit>
      </record>
      <groupexit>

      </groupexit>
   </group>
</moml>
The following implements the same functionality, as described above,
in an alternate mechanism, using the <record> composite mechanism for
the play and record operation.
<?xml version="1.0" encoding="UTF-8"?>
<moml version="1.0" id="12345">
  <record prespeech= 3s postspeech= 5s maxtime="60s" termkey= #</pre>
              dest="file://record.wav" format="g729">
      <play barge= true >
         <audio uri="file://prompt.wav"/>
      </play>
      <recordexit>
         <send target="source" event="done"</pre>
               namelist="record.len record.end"/>
      </recordexit>
  </record>
```

</moml>

### **16.4** Speech Recognition

The following simple example requests that a user speak the name of a city and returns the result.

Saleem & Sharratt Expires - April 2006

```
Internet-draft
                 Media Objects Markup Language (MOML)
                                                           October 2005

               namelist="dtmf.digits dtmf.end"/>
      </groupexit>
  </group>
</moml>
The following implements the same functionality, as described above,
in an alternate mechanism, using the <collect> composite mechanism
for the play and collect operation.
<?xml version="1.0" encoding="UTF-8"?>
<moml version="1.0" id="12345">
   <collect fdt="10s" idt="16s">
      <play barge= true >
         <audio uri="file://prompt.wav"/>
      </play>
      <pattern digits="xxxx#">
         <send target="source" event="done"</pre>
               namelist="dtmf.digits dtmf.end"/>
      </pattern>
      <noinput>
         <send target="source" event="done"</pre>
               namelist="dtmf.end"/>
      </noinput>
      <nomatch>
         <send target="source" event="done"</pre>
               namelist="dtmf.end"/>
      </nomatch>
   </dtmf>
```

</moml>

Saleem & Sharratt

#### **16.6** User Controlled Gain

This shows an example of nesting groups to create an arbitrary full duplex media control. DTMF is detected on media flowing in one direction and used to adjust the gain applied to media flowing in the opposite direction. Additionally, the stream which is used to detect DTMF has DTMF removed and its gain automatically adjusted before leaving the group. This widget could be used between a conference participant and a conference mixer.

```
<?xml version="1.0" encoding="UTF-8"?>
<moml version="1.0" id="12345">
  <group topology="fullduplex">
      <group topology="parallel">
         <dtmf>
            <pattern digits="1" iterate="forever">
               <send target="gain" event="louder"/>
            </pattern>
            <pattern digits="2" iterate="forever">
               <send target="gain" event="softer"/>
            </pattern>
         </dtmf>
         <group topology="serial">
            <clamp/>
            <agc tgtlvl="0"/>
         </group>
      </group>
      <gain amt="0" incr="5"/>
   </group>
</moml>
```

#### **17**. Change Summary

The following are the changes between the -06 version of the draft and the -05 version:

- o added support for video play and video record
- o added ability for record operation to make separate audio and video recordings, as well as combined audio and video recording
- o added functionality to allow MOML scripts using play, to optionally specify and override the audio and video format attributes from the media file
- o added functionality to allow MOML scripts using record, to optionally specify audio and video format attributes to be used when creating the recorded file

- o added new Package Scheme section describing the ability and process for defining new MOML packages
- o added composite functions (play/collect and play/record) using <collect> and <record> elements
- o added <play> as valid child element for <dtmf> or <collect>
- o added <play> as valid child element for <record>
- o added new element named <collect>, which is identical to <dtmf>
- o added notes to Overview section to define and describe differences between the Media Primitives and Composites model and the Media Groups model.
- o added sample MOML script for play and collection operation using the Media Primitives and Composites model. (See section 13.5)
- o added sample MOML script for play and record operation using the Media Primitives and Composites model. (See section 13.5)
- o added RFC 2119 conformance section and related updates

The following are the changes between the -05 version of the draft and the -04 version:

o no changes.

The following are the primary changes between -04 version of the draft and the -01 version:

- o specified the use of MOML directly in SIP (see section 4)
- o specified the <event> element for notifying events in SIP INFO messages
- o added <qate> transform primitive which can gate the flow of media regardless of its format
- o extended sending events to "source" to allow event names specific to the source naming conventions to be included. This can allow such features as the source relaying an event to another MOML object it has created.
- o modularized the language and specified rules to extend it in order to allow it to be independently tailored to different environments and platforms (see section 5)

Between the -O1 version and the -OO version the changes were:

- o added primitives to detect, send, and receive fax
- o added "xml:lang" attribute to <play> <audio> <var> and <tts>.
   children of <play> inherit from play unless overridden.
- o allow the uri in <audio> to refer to a logical clip (physical determined by language) and sequence as well as a physical clip (for local uri references).
- o restructured the schema as a partial step towards modularization and the ability to subset and extend the language in a standards compliant manner.
- o made <dtmfgen> to be the same level as <play> and not a child
   of <play>
- o changed "pipe" and "star" to be "serial" and "parallel"
- o made all termination events consistently use the root
   "terminate". previously some primitives used the root "stop"
- o changed "max" attribute to "iterate" for the <dtmf>, <pattern>, <noinput>, and <nomatch>, and <speech> elements.
- o change "iterations" attribute of <play> and <audio> to "iterate".
- o removed explicit "lhs" / "rhs" labeling of full duplex objects

## **18**. XML Schema

The base MOML schema defines the <moml> element and includes all of the modules which together define the full language. The <moml> element defines that a given document may be either a request to a media server or an event notified by a media server.

```
<?xml version="1.0" encoding="UTF-8"?>
<xs:schema elementFormDefault="unqualified"
attributeFormDefault="unqualified"
xmlns:xs="http://www.w3.org/2001/XMLSchema">
<xs:include schemaLocation="moml-group-module.xsd"/>

### Security Considerations

MOML is invoked through other languages and protocols and as such security considerations depend on those environments.

MOML being an XML based language, security considerations as defined by RFC 3023 [14] are applicable.

## IANA Considerations

IANA registration for 'application/moml+xml' media type is planned.

MGCP and Megaco/H.248 packages are registered with IANA so that there is no conflict between packages developed by different authors. The

Saleem & Sharratt

Expires - April 2006

package scheme planned for future extensibility of MSML/MOML will also require IANA registry of packages.

#### Acknowledgments

Version -06 was derived from earlier versions co-authored by Tim Melanchuk (contact: <tim.melanchuk@gmail.com>) and Garland Sharratt. Adnan Saleem and Yong Xin of Convedia, have provided key insights, both theoretic and through development experience, on several versions of the drafts. Stephen Buko and George Raskulinec of Intel made numerous valuable contributions for new feature additions to MSML and MOML versions 06. Gilles Compienne of Ubiquity Software has provided feedback on several versions of this draft. Chris Boulton and Ben Smith, both of Ubiquity, and Michael Rice of VocalData helped clarify several issues in the -00 draft, while Bruce Walsh and Kevin Fitzgerald, both of Spectel, provided important feedback on that draft. Cliff Schornak of Commetrex significantly contributed to the facsimile work.
