

Synchronization operations for disconnected IMAP4 clients

Status of this Memo

This document is an Internet Draft and is in full conformance with all provisions of [Section 10 of RFC 2026](#).

Internet Drafts are working documents of the Internet Engineering Task Force (IETF), its Areas, and its Working Groups. Note that other groups may also distribute working documents as Internet Drafts. Internet Drafts are draft documents valid for a maximum of six months. Internet Drafts may be updated, replaced, or obsoleted by other documents at any time. It is not appropriate to use Internet Drafts as reference material or to cite them other than as ``work in progress''.

The list of current Internet-Drafts can be accessed at <http://www.ietf.org/ietf/1id-abstracts.txt>

The list of Internet-Draft Shadow Directories can be accessed at <http://www.ietf.org/shadow.html>.

This is a draft document based on the expired draft written by the IETF IMAP Working Group. A revised version of this draft document will be submitted to the RFC editor as an Informational RFC for the Internet Community. Discussion and suggestions for improvement are requested, and should be sent to imap@CAC.Washington.EDU.

This memo is for informational use and does not constitute a standard. Distribution of this memo is unlimited.

1. Abstract

This document attempts to address some of the issues involved in building a disconnected IMAP4 client. In particular, it deals with the issues of what might be called the "driver" portion of the synchronization tool: the portion of the code responsible for issuing the correct set of IMAP4 commands to synchronize the disconnected client in the way that is most likely to make the human who uses the disconnected client happy.

This note describes different strategies that can be used by disconnected clients as well as shows how to use IMAP protocol in order to minimize the time of synchronization process.

2. Conventions Used in this Document

In examples, "C:" and "S:" indicate lines sent by the client and server respectively.

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC 2119](#) [[KEYWORDS](#)].

Editorial comments/questions or missing paragraphs are marked in the text with << and >>.

3. Design Principles

All mailbox state or content information stored on the disconnected client should be viewed strictly as a cache of the state of the server. The "master" state remains on the server, just as it would with an interactive IMAP4 client. The one exception to this rule is that information about the state of the disconnected client's cache (the state includes flag changes while offline and scheduled message uploads) remains on the disconnected client: that is, the IMAP4 server is not responsible for remembering the state of the disconnected IMAP4 client.

We assume that a disconnected client is a client that, for whatever reason, wants to minimize the length of time that it is "on the phone" to the IMAP4 server. Often this will be because the client is using a dialup connection, possibly with very low bandwidth, but sometimes it might just be that the human is in a hurry to catch an airplane, or some other event beyond our control. Whatever the reason, we assume that we must make efficient use of the network connection, both in the usual sense (not generating spurious traffic) and in the sense that we would prefer not to have the connection sitting idle while the client and/or the server is performing strictly local computation or I/O. Another, perhaps simpler way of stating this is that we assume that network connections are "expensive".

Practical experience with disconnected mail systems has shown that there is no single synchronization strategy that is appropriate for all cases. Different humans have different preferences, and the same human's preference will vary depending both on external circumstance (how much of a hurry the human is in today) and on the value that the human places on the messages being transferred. The point here is that there is no way that the synchronization program can guess exactly what the human wants to do, so the human will have to provide some guidance.

Taken together, the preceding two principles lead to the conclusion that the synchronization program must make its decisions based on

some kind of guidance provided by the human by selecting the appropriate options in UI or through some sort of configuration file, but almost certainly should not pause for I/O with the human during the middle of the synchronization process. The human will almost certainly have several different configurations for the synchronization program, for different circumstances.

Since a disconnected client has no way of knowing what changes might have occurred to the mailbox while it was disconnected, message numbers are not useful to a disconnected client. All disconnected client operations should be performed using UIDs, so that the client can be sure that it and the server are talking about the same messages during the synchronization process.

4. Overall picture of synchronization

The basic strategy for synchronization is outlined below.

Note that the real strategy may vary from one application to another or may depend on a synchronization mode.

- a) Process any "actions" that were pending on the client that were not associated with any mailbox (in particular sending messages composed offline with SMTP. This is not part of IMAP synchronization, but it is mentioned here for completeness);
- b) Fetch the current list of "interesting" mailboxes (The disconnected client should allow the user to skip this step completely);
- c) "Client-to-server synchronization" - for each IMAP "action" that were pending on the client:
 - 1) If the action implies opening a new mailbox (any operation that operates on messages) - open the mailbox. Check its UID validity value (see [section 5.1](#) for more details) returned in the UIDVALIDITY response code. If the UIDVALIDITY value returned by the server differs, the client MUST empty the local cache of the mailbox and remove any pending "actions" which refer to UIDs in that mailbox.
 - 2) Perform the action. If the action is to delete a mailbox (DELETE), make sure that the mailbox is closed first.
- d) "Server-to-client synchronization" - for each mailbox that requires synchronization, do the following:
 - 1) Check the mailbox UIDVALIDITY (see [section 5.1](#) for more details). with SELECT/EXAMINE/STATUS.
If UIDVALIDITY value returned by the server differs, the client MUST
 - * empty the local cache of that mailbox;

- * remove any pending "actions" which refer to UIDs in that mailbox;
 - * skip step 2-II;
- 2) Fetch the current "descriptors";
 - I) Discover new messages.
 - II) Discover changes to old messages.
 - 3) Fetch the bodies of any "interesting" messages that the client doesn't already have.
 - d) Close all open mailboxes not required for further operations (if staying online) or disconnect all open connections (if going offline).

Terms used:

"Actions" are queued requests that were made by the human to the client's MUA software while the client was disconnected.

Let define "descriptors" as a set of IMAP4 FETCH data items. Conceptually, a message's descriptor is that set of information that allows the synchronization program to decide what protocol actions are necessary to bring the local cache to the desired state for this message; since this decision is really up to the human, this information probably includes at least a few header fields intended for human consumption. Exactly what will constitute a descriptor depends on the client implementation. At a minimum, the descriptor contains the message's UID and FLAGS. Other likely candidates are the [RFC822](#).SIZE, [RFC822](#).HEADER and BODYSTRUCTURE data items.

Comments:

- 1). The list of actions should be ordered. E.g., if the human deletes message A1 in mailbox A, then expunges mailbox A, then deletes message A2 in mailbox A, the human will expect that message A1 is gone and that message A2 is still present but is now deleted.

By processing all the actions before proceeding with synchronization, we avoid having to compensate for the local MUA's changes to the server's state. That is, once we have processed all the pending actions, the steps that the client must take to synchronize itself will be the same no matter where the changes to the server's state originated.

- 2). Steps a) and b) can be performed in parallel. Alternatively step a) can be performed after d).
- 3). On step b) the set of "interesting" mailboxes pretty much has to be

determined by the human. What mailboxes belong to this set may vary between different IMAP4 sessions with the same server, client, and human. An interesting mailbox can be a mailbox returned by LSUB command. Special mailbox "INBOX" SHOULD always be considered "interesting".

- 4). On step d-2-II) the client also finds out about changes to the flags of messages that the client already has in its local cache, as well as finding out about messages in the local cache that no longer exist on the server (i.e., messages that have been expunged).
- 5). "Interesting" messages are those messages that the synchronization program thinks the human wants to have cached locally, based on the configuration and the data retrieved in step (b).

The rest of this discussion will focus primarily on the synchronization issues for a single mailbox.

5. Mailbox synchronization steps and strategies

5.1. Checking UID Validity

The "UID validity" of a mailbox is a number returned in an UIDVALIDITY response code in an OK untagged response at mailbox selection time. The UID validity value changes between sessions when UIDs fail to persist between sessions.

Whenever the client selects a mailbox, the client must compare the returned UID validity value with the value stored in the local cache. If the UID validity values differ, the UIDs in the client's cache are no longer valid. The client MUST then empty the local cache of that mailbox and remove any pending "actions" which refer to UIDs in that mailbox. The client MAY also issue a warning to the human. The client MUST NOT cancel any scheduled uploads (i.e. APPENDs) for the mailbox.

Note that UIDVALIDITY is not only returned on a mailbox selection. COPYUID and APPENDUID response codes defined in [UIDPLUS] extension (see also 5.2.2) and UIDVALIDITY STATUS response data item also contain a UIDVALIDITY value for some other mailbox. The client SHOULD behave as described in the previous paragraph (but it should act on the other mailbox's cache), no matter how it obtained the UIDVALIDITY value.

5.2. Synchronizing local changes with the server

5.2.1. Uploading messages to the mailbox

There are two most typical examples of operations that will result in

message

uploads:

- 1) Saving a draft message
- 2) Message copy between remote mailboxes on two different IMAP servers or a local mailbox and a remote mailbox.

Message upload is performed with APPEND command. A message scheduled to be uploaded has no UID associated with it, as all UIDs are assigned by the server. The APPEND command will effectively associate a UID with the

uploaded

message that can be stored in the local cache for a future reference.

However [[IMAP4](#)] doesn't describe a simple mechanism to discover the message

UID

by just performing the APPEND command. In order to discover UID the client

can

do one of the following:

- 1) Remove the uploaded message from cache. After that use the mechanism described in 5.3 to fetch the information about the uploaded message as if it was uploaded by some other client.

- 2) Try to fetch header information as described in 5.2.2 in order to find a message that corresponds to the uploaded message. One strategy of doing that is described in 5.2.2.

Case 1) describes a non particularly smart client.

```
C: A003 APPEND Drafts (\Seen $MDNSent) {310}
S: + Ready for literal data
C: Date: Mon, 7 Feb 1994 21:52:25 -0800 (PST)
C: From: Fred Foobar <foobar@Blurdybloop.COM>
C: Subject: afternoon meeting
C: To: mooch@owatagu.siam.edu
C: Message-Id: <B27397-0100000@Blurdybloop.COM>
C: MIME-Version: 1.0
C: Content-Type: TEXT/PLAIN; CHARSET=US-ASCII
C:
C: Hello Joe, do you think we can meet at 3:30 tomorrow?
C:
S: A003 OK APPEND Completed
```

Fortunately there is a simpler way to discover the message UID in the presence

of [[UIDPLUS](#)] extension:

```
C: A003 APPEND Drafts (\Seen $MDNSent) {310}
```

```
S: + Ready for literal data
C: Date: Mon, 7 Feb 1994 21:52:25 -0800 (PST)
C: From: Fred Foobar <foobar@Blurdybloop.COM>
C: Subject: afternoon meeting
C: To: mooch@owatagu.siam.edu
C: Message-Id: <B27397-0100000@Blurdybloop.COM>
C: MIME-Version: 1.0
C: Content-Type: TEXT/PLAIN; CHARSET=US-ASCII
C:
C: Hello Joe, do you think we can meet at 3:30 tomorrow?
C:
S: A003 OK APPEND [APPENDUID 1022843275 77712] completed
```

The UID of the appended message is the second parameter of APPENDUID response code.

5.2.2. Optimizing "move" and "copy" operations

Practical experience with IMAP, and other mailbox access protocols that support multiple mailboxes suggests that moving a message from one mailbox to another is an extremely common operation.

5.2.2.1. Moving a message between two mailboxes on the same server

In IMAP4 a "move" operation between two mailboxes on the same server is really a combination of a COPY operation and a STORE +FLAGS (\Deleted) operation. This makes good protocol sense for IMAP, but it leaves a simple-minded disconnected client in the silly position of deleting and possibly expunging its cached copy of a message, then fetching an identical copy via the network.

However, the presence of UIDPLUS extension support in the server can help:

```
A001 UID COPY 567,414 "Interesting Messages"
```

```
A001 OK [COPYUID 1022843275 414,567 5:6] Completed
```

This tells the client that the message with UID 414 in the current mailbox was successfully copied to the mailbox "Interesting Messages" and was given the UID 5, and that the message with UID 567 was given the UID 6.

In the absence of UIDPLUS extension support in the server the following trick can be used. By including the Message-ID: header and the INTERNALDATE data item as part of the descriptor, the client can check the descriptor of

a

"new" message against messages that are already in its cache, and avoid fetching the extra copy. Of course, it's possible that the cost of checking to see if the message is already in the local cache may exceed the cost of just fetching it, so this technique should not be used blindly. If the MUA implements a "move" command, it make special provisions to use this technique when it knows that a copy/delete sequence is the result of a "move" command.

Since it's theoretically possible for this algorithm to find the wrong message (given sufficiently malignant Message-ID headers), implementors should provide a way to disable this optimization, both permanently and on a message-by-message basis.

<< Example >>

5.2.2.2. Moving a message from a remote mailbox to a local

Moving a message from a remote mailbox to a local is done with FETCH (that includes FLAGS and INTERNALDATE) followed by UID STORE <uid> +FLAGS.SILENT (\Deleted):

```
C: A003 UID FETCH 123 (RFC822 INTERNALDATE FLAGS)
S: * 27 FETCH (UID 123 INTERNALDATE "31-May-2002 05:26:59 -0600"
  FLAGS (\Seen $MDNSent) RFC822
S: ...message body...
S: )
S: A003 OK UID FETCH completed
C: A004 UID STORE <uid> +FLAGS.SILENT (\Deleted)
S: A004 STORE completed
```

Note, that there is no reason to fetch the message during synchronization if it already in the client's cache. Also, the client SHOULD preserve delivery date in the local cache.

5.2.2.3. Moving a message from a local mailbox to a remote

Moving a message from a local mailbox to a remote is done with APPEND:

```
C: A003 APPEND Drafts (\Seen $MDNSent) "31-May-2002 05:26:59 -0600" {310}
S: + Ready for literal data
C: Date: Mon, 7 Feb 1994 21:52:25 -0800 (PST)
C: From: Fred Foobar <foobar@Blurdybloop.COM>
C: Subject: afternoon meeting
C: To: mooch@owatagu.siam.edu
C: Message-Id: <B27397-0100000@Blurdybloop.COM>
C: MIME-Version: 1.0
C: Content-Type: TEXT/PLAIN; CHARSET=US-ASCII
C:
C: Hello Joe, do you think we can meet at 3:30 tomorrow?
C:
S: A003 OK APPEND [APPENDUID 1022843275 77712] completed
```

The client SHOULD specify delivery date from the local cache in the APPEND.

5.2.2.4. Moving a message between two mailbox on two different servers

Moving a message between two mailbox on two different servers is a

combination of the 5.2.2.2 followed by 5.2.2.3.

5.2.2.5. Uploading multiple messages to a remote mailbox with MULTIAPPEND

When there is a need to upload multiple messages to a remote mailbox (e.g. as per 5.2.2.3), the presence of certain IMAP extensions may significantly improve performance. One of them is [\[MULTIAPPEND\]](#).

For some mail stores opening a mailbox for appending might be expensive. [\[MULTIAPPEND\]](#) tells the server to open mailbox once (instead of opening and closing it "n" times per "n" messages to be uploaded) and keep it open while a group of messages is being uploaded to the server.

Also, if the server supports both [\[MULTIAPPEND\]](#) and [\[LITERAL+\]](#) extensions, the entire upload is accomplished in a single command/response round trip.

Note: Client implementors should be aware, that [\[MULTIAPPEND\]](#) performs append of multiple messages atomically. This means, for example, if there is not enough space to save "n"-th message (or the message has invalid structure and is rejected by the server) after successful upload of "n-1" messages, the whole upload operation fails and no message will be saved in the mailbox. Although, this behavior might be desirable in certain situations, it might not be what you want. See also [section 6.1](#) for discussions of error recovery.

Note: MULTIAPPEND can be used together with UIDPLUS extension in a way similar to what was described in [section 5.2.1](#). [\[MULTIAPPEND\]](#) extends syntax of APPENDUID response code to allow for multiple message UIDs in the second parameter.

Example:

An example below demonstrates the use of MULTIAPPEND together with UIDPLUS (synchronization points where the client waits for confirmations from the server are marked with "<--->"):

```
C: A003 APPEND Jan-2002 (\Seen $MDNSent) "31-May-2002 05:26:59
-0600" {310}
<--->
S: + Ready for literal data
C: Date: Mon, 7 Feb 1994 21:52:25 -0800 (PST)
C: From: Fred Foobar <foobar@Blurdybloop.COM>
C: Subject: afternoon meeting
C: To: mooch@owatagu.siam.edu
C: Message-Id: <B27397-0100000@Blurdybloop.COM>
C: MIME-Version: 1.0
C: Content-Type: TEXT/PLAIN; CHARSET=US-ASCII
C:
C: Hello Joe, do you think we can meet at 3:30 tomorrow?
C: (\Seen) " 1-Jun-2002 22:43:04 -0800" {286}
<--->
```

```

S: + Ready for literal data
C: Date: Mon, 7 Feb 1994 22:43:04 -0800 (PST)
C: From: Joe Mooch <mooch@OWaTaGu.siam.EDU>
C: Subject: Re: afternoon meeting
C: To: foobar@blurdybloop.com
C: Message-Id: <a0434793874930@OWaTaGu.siam.EDU>
C: MIME-Version: 1.0
C: Content-Type: TEXT/PLAIN; CHARSET=US-ASCII
C:
C: 3:30 is fine with me.
C:
S: A003 OK APPEND [APPENDUID 1022843275 77712,77713] completed

```

The upload takes 3 round trips.

Example:

The example above was modified for the case when the server supports MULTIAPPEND, LITERAL+ and UIDPLUS. The upload takes only 1 round trip.

```

C: A003 APPEND Jan-2002 (\Seen $MDNSent) "31-May-2002 05:26:59
-0600" {310+}
C: Date: Mon, 7 Feb 1994 21:52:25 -0800 (PST)
C: From: Fred Foobar <foobar@Blurdybloop.COM>
C: Subject: afternoon meeting
C: To: mooch@owatagu.siam.edu

C: MIME-Version: 1.0
C: Content-Type: TEXT/PLAIN; CHARSET=US-ASCII
C:
C: 3:30 is fine with me.
C:
S: A003 OK APPEND [APPENDUID 1022843275 77712,77713] completed

```

5.2.3. Replaying local flag changes

The disconnected client uses STORE command to synchronize local flag state with the server. The disconnected client SHOULD use +FLAGS.SILENT or -FLAGS.SILENT in order to set or unset flags modified by the user while offline. FLAGS form must not be used, as there is a risk that this will overwrite flags

on the server that has been changed by some other client.

Example:

For the message with UID 15, the disconnected client stores the following flags \Seen and \$Highest. The flags were modified on the server by some other

client: \Seen, \Answered and \$Highest.

While offline the user requested to remove \$Highest flags and to add \Deleted.

The flag synchronization sequence for the message should look like:

```
C: A001 UID STORE 15 +FLAGS.SILENT (\Deleted)
S: A001 STORE completed
C: A002 UID STORE 15 -FLAGS.SILENT ($Highest)
S: A002 STORE completed
```

If the disconnected client is able to store an additional binary state information (or a piece of information that can take a value from a predefined

set of values) in the local cache of an IMAP mailbox or in a local mailbox (e.g. message priority), and if the server supports storing of arbitrary keywords, the client MUST use keywords to store this state on the server.

Example:

Imagine a speculative mail client that can mark a message as one of work-related

(\$Work), personal (\$Personal) or spam (\$Spam). In order to mark a message as

personal the client issues:

```
C: A001 UID STORE 15 +FLAGS.SILENT ($Personal)
S: A001 STORE completed
C: A002 UID STORE 15 -FLAGS.SILENT ($Work $Spam)
S: A002 STORE completed
```

In order to mark the message as neither work, nor personal, not spam, the client

issues:

```
C: A003 UID STORE 15 -FLAGS.SILENT ($Personal $Work $Spam)
S: A003 STORE completed
```

5.2.4. Processing mailbox compression (expunge) requests

A naive disconnected client implementation that supports compressing a mailbox

while offline may decide to issue an EXPUNGE command to the server in order to expunge messages marked \Deleted. The problem with this command during synchronization is that it permanently erases all messages with \Deleted flag set,

i.e. even those messages that were marked as \Deleted on the server while

the user

was offline. Doing so will lead the user to an unpleasant surprise.

Fortunately [[UIDPLUS](#)] extension can help in this case as well. The extension introduces UID EXPUNGE command, that, unlike EXPUNGE, takes a UID set parameter,

that lists UIDs of all messages that can be expunged. When processing this command

server erases only messages with \Deleted flag listed in the UID list. Thus, a message not listed in the UID set will not be expunged even if it has \Deleted flag set.

Example: While offline 3 messages with UIDs 7, 27 and 65 were marked \Deleted

when the user requested to compress the open mailbox. Another client marked

a message \Deleted on the server (UID 34). During synchronization the disconnected client issues:

```
C: A001 UID EXPUNGE 7,27,65
S: * ... EXPUNGE
S: * ... EXPUNGE
S: * ... EXPUNGE
S: A001 UID EXPUNGE completed
```

If another client issues UID SEARCH DELETED command (to find all messages with

\Deleted flag) before and after the UID EXPUNGE it will get:

Before:

```
C: B001 UID SEARCH DELETED
S: * SEARCH 65 34 27 7
S: B001 UID SEARCH completed
```

After:

```
C: B002 UID SEARCH DELETED
S: * SEARCH 34
S: B002 UID SEARCH completed
```

In the absence of [[UIDPLUS](#)] extension the following sequence of command can be

used as an approximation. Note, that when this sequence is performed, there is a

possibility that another client marks additional messages as deleted and these messages will be expunged as well.

1). Find all messages marked \Deleted on the server:

```
C: A001 UID SEARCH DELETED
```

```
S: * SEARCH 65 34 27 7
S: A001 UID SEARCH completed
```

2). Find all messages that must not be erased (for the previous example the list will consist of the message with UID 34)

3). Temporary remove \Deleted flag on all messages found on the step 2)

```
C: A002 UID STORE 34 -FLAGS.SILENT (\Deleted)
S: A002 UID STORE completed
```

4). Expunge the mailbox

```
C: A003 EXPUNGE
S: * 20 EXPUNGE
S: * 7 EXPUNGE
S: * 1 EXPUNGE
S: A003 EXPUNGE completed
```

Here message with UID 7 has message number 1; with UID 27 - message number 7 and with UID 65 - message number 20.

5). Restore \Deleted flag on all messages found when performing step 2)

```
C: A004 UID STORE 34 +FLAGS.SILENT (\Deleted)
S: A004 UID STORE completed
```

5.2.5. Closing a mailbox

When the disconnected client has to close a mailbox, it SHOULD NOT use CLOSE command, because CLOSE does a silent EXPUNGE ([section 5.2.4](#) explains why EXPUNGE must not be used by a disconnected client). It is safe to use CLOSE only if the mailbox was opened with EXAMINE.

If the mailbox was opened with SELECT, the client can use one of the following commands to implicitly close the mailbox and prevent the silent expunge:

- 1). UNSELECT - This is a command described in [[UNSELECT](#)] that works as CLOSE, but doesn't cause the silent EXPUNGE. This command is supported by the server if it reports UNSELECT in its CAPABILITY list.
- 2). SELECT <another_mailbox> - SELECT causes implicit CLOSE without EXPUNGE.
- 3). If the client intends to issue LOGOUT after closing the mailbox, it may just issue LOGOUT, because LOGOUT causes implicit CLOSE without EXPUNGE as well.
- 4). SELECT <non_existing_mailbox> - if the client knows a mailbox that doesn't exist or can't be selected, it MAY SELECT it.

If the client opened the mailbox with SELECT and just wants to avoid implicit EXPUNGE without closing the mailbox, it may also use the following:

5). EXAMINE <mailbox> - reselect the same mailbox in read-only mode.

5.3. Details of "Normal" synchronization of a single mailbox

The most common form of synchronization is where the human trusts the integrity of the client's copy of the state of a particular mailbox, and simply wants to bring the client's cache up to date so that it accurately reflects the mailbox's current state on the server.

5.3.1. Discovering new messages and changes to old messages

Let <lastseenuid> represent the highest UID that the client knows about in this mailbox. Since UIDs are allocated in strictly ascending order, this is simply the UID of the last message in the mailbox that the client knows about. Let <lastseenuid+1> represent <lastseenuid>'s UID plus one. Let <descriptors> represent a list consisting of all the FETCH data item items that the implementation considers to be part of the descriptor; at a minimum this is just the FLAGS data item, but it usually also includes BODYSTRUCTURE and [RFC822](#).SIZE. At this step <descriptors> SHOULD NOT include [RFC822](#).

With no further information, the client can issue the following two commands:

```
tag1 UID FETCH <lastseen+1>:* <descriptors>
tag2 UID FETCH 1:<lastseenuid> FLAGS
```

The first command will request some information about "new" messages (i.e. messages received by the server since the last synchronization). It will also allow the client to build a message number to UID map (only for new messages). The second command allows the client to

- 1) update cached flags for old messages;
- 2) find out which old messages got expunged;
- 3) build a mapping between message numbers and UIDs (for old messages).

The order here is significant. We want the server to start returning the list of new message descriptors as fast as it can, so that the client can start issuing more FETCH commands, so we start out by asking for the descriptors of all the messages we know the client cannot possibly have cached yet. The second command fetches the information we need to determine what changes may have occurred to messages that the client already has cached. Note, that the latter command should only be issued if the UIDNEXT value cached by the client differs from the one returned by the server. Once the client has issued these two commands, there's nothing more the client can do with this mailbox until the responses to the first command start arriving. A clever synchronization program might use this time to fetch its local cache state from disk, or start the process of synchronizing another mailbox.

Example of the first FETCH:

```
C: A011 UID fetch 131:* (FLAGS BODYSTRUCTURE INTERNALDATE RFC822.SIZE)
S: ...
```

The second FETCH command will result in nil or more untagged fetch responses. Each response will have a corresponding UID FETCH data item. All messages that didn't have a matching untagged FETCH response MUST be removed from the local cache.

For example, if the <lastseenuid> had a value 15000 and the local cache contained 3 messages with the UIDs 12, 777 and 14999 respectively, than after receiving the following responses from the server:

```
S: * 1 FETCH (UID 12 FLAGS (\Seen))
S: * 2 FETCH (UID 777 FLAGS (\Answered \Deleted))
```

the client must remove the message with UID 14999 from its local cache.

Note: If the client is not interested in flag changes (i.e. the client only wants to know which old messages are still on the server), the second FETCH command can be substituted with:

```
tag2 UID SEARCH UID 1:<lastseenuid>
```

This command will generate less traffic. However an implementor should be aware that in order to build the mapping table from message numbers to UIDs the output of the SEARCH command MUST be sorted first, because there is no requirement for a server to return UIDs in SEARCH response in the ascending order.

[5.3.2](#). Searching for "interesting" messages.

This step is either performed entirely on the client (from the information received

in step 5.3.1), after performing additional searches on the server or both.

The decision on what is an "interesting" message is up to the client software

and the human. One easy criterion that should probably be implemented in any

client is whether the message is "too big" for automatic retrieval, where "too big"

is a parameter defined in the client's configuration.

Another commonly used criteria is the age of a message. For example, the client

may choose to download only messages received in the last week (in this case, <date>

would be today's date minus 7 days):

```
tag3 UID SEARCH UID <uidset> SINCE <date>
```

Keep in mind that a date search disregards time and timezone.

The client can avoid doing this search if it specified INTERNALDATE in <descriptors>

on step 5.3.1. If the client did, it can perform the search itself.

At this step the client also decides what kind of information about a particular

message to fetch from the server. In particular, even for a message that is considered

to be "too big" the client MAY choose to fetch some part(s) of it. For example,

if the message is a multipart/mixed containing a text part and a MPEG attachment,

there is no reason for the client not to fetch the text part. The decision of which

part should or should not be fetched can be based on the information received in

BODYSTRUCTURE FETCH response data item (i.e. if BODYSTRUCTURE was included in

<descriptors> on step 5.3.1).

5.3.3. Populating cache with "interesting" messages.

Once the client found out which messages are "interesting", the client can start issuing appropriate FETCH commands for "interesting" messages or bodyparts thereof.

It is important to note that fetching a message into the disconnected client's local cache does NOT imply that the human has (or even will) read the message. Thus, the synchronization program for a disconnected client should always be careful to use the .PEEK variants of the FETCH data items that implicitly set the \Seen flag.

Once the last descriptor has arrived and the last FETCH command has been issued, the client simply needs to process the incoming fetch items, using them to update the local message cache.

In order to avoid deadlock problems, the client must give processing of received messages priority over issuing new FETCH commands during this synchronization process. This may necessitate temporary local queuing of FETCH requests that cannot be issued without causing a deadlock. In order to achieve the best use of the "expensive" network connection, the client will almost certainly need to pay careful attention to any flow-control information that it can obtain from the underlying transport connection (usually a TCP connection).

Example: After fetching a message BODYSTRUCTURE the client discovers a complex MIME message. Then it decides to fetch MIME headers of the nested MIME messages and some body parts.

```

C: A011 UID fetch 11 (BODYSTRUCTURE)
S: ...
C: A012 UID fetch 11 (BODY[HEADER] BODY[1.MIME] BODY[1.1.MIME]
    BODY[1.2.MIME] BODY[2.MIME] BODY[3.MIME] BODY[4.MIME] BODY[5.MIME]
    BODY[6.MIME] BODY[7.MIME] BODY[8.MIME] BODY[9.MIME] BODY[10.MIME]
    BODY[11.MIME] BODY[12.MIME] BODY[13.MIME] BODY[14.MIME] BODY[15.MIME]
    BODY[16.MIME] BODY[17.MIME] BODY[18.MIME] BODY[19.MIME] BODY[20.MIME]
    BODY[21.MIME])
S: ...
C: A013 UID fetch 11 (BODY[1.1] BODY[1.2])
S: ...
C: A014 UID fetch 11 (BODY[3] BODY[4] BODY[5] BODY[6] BODY[7] BODY[8]
    BODY[9] BODY[10] BODY[11] BODY[13] BODY[14] BODY[15] BODY[16]
    BODY[21])
S: ...

```

5.3.4. User initiated synchronization

After the client finished the main synchronization that was described in 5.3.1-5.3.3 the user may optionally request additional synchronization steps while the client is still online. This is not any different from the process described in 5.3.2 and 5.3.3.

Typical examples are:

- 1) fetch all messages selected in UI.
- 2) fetch all messages marked as \Flagged on the server.

5.4. Special case: descriptor-only synchronization

For some mailboxes, fetching the descriptors might be the entire synchronization step. Practical experience with IMAP has shown that a certain class of mailboxes (e.g., "archival" mailboxes) are used primarily for long-term storage of important messages that the human wants to have instantly available on demand but does not want cluttering up the disconnected client's cache at any other time. Messages in this kind of mailbox would be fetched exclusively by explicit actions queued by the local MUA. Thus, the only synchronization that is necessary for a mailbox of this kind is fetching the descriptor information that the human will use to identify messages that should be explicitly fetched.

Special mailboxes that receive traffic from a high volume, low priority mailing list might also be in this category, at least when the human is in a hurry.

5.5. Special case: fast new-only synchronization

In some cases the human might be in such a hurry that s/he doesn't care about changes to old messages, just about new messages. In this

case, the client can skip the UID FETCH command that obtains the flags and UIDs for old messages (1:<lastseenuid>).

5.6. Special case: blind FETCH

In some cases the human may know (for whatever reason) that s/he always wants to fetch any new messages in a particular mailbox, unconditionally. In this case, the client can just fetch the messages themselves, rather than just the descriptors, by using a command like:

```
tag1 UID FETCH <lastseen+1>:* (FLAGS RFC822.PEEK)
```

Note, that this example ignores the fact that the messages can be arbitrary long. The disconnected client MUST always check for message size before downloading, unless explicitly told otherwise. A good behaving client should use instead something like the following:

- 1) Issue "tag1 UID FETCH <lastseen+1>:* (FLAGS [RFC822](#).SIZE)"
- 2) From the message sizes returned in step 1 construct UID set <required_messages>
- 3) Issue "tag2 UID FETCH <required_messages> ([RFC822](#).PEEK)"

or

- 1) Issue "tag1 UID FETCH <lastseen+1>:* (FLAGS)"
- 2) Construct UID set <old_uids> from the responses of 1)
- 3) Issue "tag2 SEARCH UID <old_uids> SMALLER <message_limit>"
Construct UID set <required_messages> from the result of the SEARCH command.
- 4) Issue "tag3 UID FETCH <required_messages> ([RFC822](#).PEEK)"

6. Implementation considerations

Below are listed some common implementation problems that should be considered when implementing a disconnected client.

golden rules that should be considered when implementing a good disconnected IMAP client.

<<*>>

- 1) Don't reorder operations during synchronization.

It is not always safe to reorder operations during synchronization, because some operations may have dependencies. So if in doubt, don't do that.

The following example demonstrates this:

Example 1: The user copies a message out of a mailbox and then deletes the mailbox.

```

C: A001 SELECT Old-Mail
S: ...
C: A002 UID COPY 111 ToDo
S: A002 OK [COPYUID 1022843345 111 94] Copy completed
...
C: A015 CLOSE
S: A005 OK Completed
C: A016 DELETE Old-Mail
S: A016 OK Mailbox deletion completed successfully

```

If the client performs DELETE (tag A016) first and COPY (tag A002) second,
 than the COPY fails.

<< Describe one case when it is safe to reorder: the disconnected client doesn't allow to perform DELETE and RENAME while offline and EXPUNGE is never used (UID EXPUNGE is used instead or its emulation as described in 5.2.3 >>

2) Implementing fake UIDs on the client.

A message scheduled to be uploaded has no UID, as UIDs are selected by the server. The client may implement fake UIDs internally in order to reference not yet uploaded messages in further operations. For example, message was scheduled to be uploaded and later marked deleted or copied to another mailbox). However, the client MUST NOT under any circumstances sent these fake UIDs to the server. Also, client implementors should be reminded that according to [\[IMAP4\]](#) an UID is a 32bit unsigned integer excluding 0. So, both 4294967295 and 2147483648 are valid UIDs and 0 and

-1

are both invalid. Existing disconnected mail clients are known to send "-1" as a message UID to servers during synchronization.

6.1. Error recovery during playback

Error recovery during synchronization is one of the trickiest parts to get right. Below, we will discuss certain error conditions and suggest possible choices to handle them:

1). Lost connection to the server.

The client MUST remember the current position in playback log and replay it starting from the interrupted operation (<<is it always safe?

>>)

next time it is connected to the same server.

<<What about operations that can produce different end result when called twice?

For example, the client is doing one of those operations (e.g. DELETE),
 connection was lost and the client doesn't know if it succeeded.

Should check for mailbox existence, instead of calling DELETE twice.>>

2). Copying/appending messages to a mailbox that doesn't exist.

The user should be advised about the situation and be given one of the following choices:

- a). Try to recreate a mailbox;
- b). Copy/upload messages to another mailbox;
- c). Skip copy/upload.
- d). Abort replay.

3). Copying messages from, rename or get/change ACLs [[ACL](#)] on a mailbox that doesn't exist:

- a). Skip operation
- b). Abort replay

4). Message to perform operation on doesn't exist.

- a). Skip operation
- b). Abort replay

<< To be completed later >>

Note 1: Several synchronization operations map to multiple IMAP commands (for example "move" described in 5.2.2). The client must guaranty atomicity of each such multistep operation. For example, when performing "move" between two mailboxes on the same server, if the server is unable to copy messages, the client MUST NOT set \Deleted flag on the messages being copied, all the more expunging them. However the client MAY consider that move operation succeeded even if the server was unable to set \Deleted flag on copied messages.

Note 2: Many synchronization operations have "data" dependencies. A failed operation should cause all dependent operations to fail as well. The client should check that and MUST NOT try to perform all dependent operations blindly (unless the user corrected the original problem). For example, a message may be scheduled to be appended to a mailbox on the server and than later on the same message may be copied to another mailbox. If the APPEND operation fails, the client must not attempt to copy message later on. (See also [Section 6](#), example 1).

[6.2.](#) Quality of implementation issues.

Below listed some quality of implementation issues for disconnected clients. They will help to write a disconnected client that works correctly, performs synchronization as quickly as possible (and thus can make the user happier as well as save her some money) and minimizes the server load:

1) Don't loose information.

- 2) Don't do work unless explicitly asked. Be flexible. Ask all questions BEFORE starting synchronization, if possible.

- 3) Minimize traffic

The client MUST NOT issue a command if the client already received the required information from the server.

The client MUST make use of UIDPLUS extension if it is supported by the server.

- 4) Minimize number of round trips.

Round trips kill performance, especially on links with high latency. Sections [5.2.2.5](#) and [6.2](#) give some advices how to minimize number of round trips.

- 5) Perform some synchronization steps in parallel, if possible.

Several synchronization steps don't depend on each other and thus can be performed in parallel. Because the server machine is usually more powerful than the client machine and can perform some operations in parallel, this may speed up the total time of synchronization.

In order to achieve such parallelization the client will have to open more than one connection to the same server. Client writers should not forget about non-trivial cost associated with establishing a TCP

connection

and performing an authentication. The disconnected client MUST NOT use a connection per each mailbox. In most cases it is sufficient to have two connections.

Any mailbox synchronization MUST start with checking of the UIDVALIDITY as described in [section 5.1](#) of this document. The client MAY use STATUS command to check UID Validity of a non selected mailbox. This is

preferable

to opening many connections to the same server to perform synchronization of multiple mailboxes simultaneously. As described in section 6.3.10 of [\[IMAP4\]](#), this SHOULD NOT be used on the selected mailbox.

[6.3. Optimizations](#)

Some useful optimizations are described in this section. A disconnected client that supports recommendations listed below will give the user a more pleasant experience.

- 1) Initial OK or PREATH responses may contain CAPABILITY response code as described in section 7.1 of [\[IMAP4\]](#). This response code gives the same information as returned by CAPABILITY command. A disconnected client that pays attention to this response code will be able to avoid sending CAPABILITY command and will save a round trip.

<< Keep mailboxes open during synchronization if possible >>

<< More to be added later >>

7. IMAP extensions that may help

The following extensions can save traffic and/or number of round trips:

- 1) The use of [[UIDPLUS](#)] is discussed in 5.1, 5.2.1, 5.2.2.1 and 5.2.4.
- 2) The use of MULTIAPPEND and LITERAL+ extensions for uploading messages is discussed in 5.2.2.5.

7.1. CONDSTORE extension

An advance disconnected mail client should use [[CONDSTORE](#)] extension when it is supported by the server. The client must cache the value from HIGHESTMODSEQ OK response code received on mailbox opening and update it whenever the server sends MODSEQ FETCH data items.

If the client receives NOMODSEQ OK untagged response instead of HIGHESTMODSEQ, it MUST remove the last known HIGHESTMODSEQ value from its cache and follow more general instructions in [section 4](#).

When the client opens the mailbox for synchronization it first compares UIDVALIDITY as described in step d)1) in [section 4](#). If the cached UIDVALIDITY value matches the one returned by the server, the client MUST compare the cached value of HIGHESTMODSEQ with the one returned by the server. If the cached HIGHESTMODSEQ value also matches the one returned by the server, then the client MUST NOT fetch flags for cached messages, as they hasn't changed. If the value on the server is higher than the cached one, the client MAY use "SEARCH MODSEQ <cached-value>" to find all messages with flags changed since the last time the client was online and had the mailbox opened. Alternatively the client MAY use "FETCH 1:* (FLAGS) (CHANGEDSINCE <cached-value>)". The latter operation combines searching for changed messages and fetching new information.

In all cases the client still need to fetch information about new messages (if requested by the user) and discover which messages got expunged.

Step d) ("Server-to-client synchronization") in [section 4](#) in the presence of CONDSTORE extension is amended as follows:

- d) "Server-to-client synchronization" - for each mailbox that requires synchronization, do the following:

1a) Check the mailbox UIDVALIDITY (see [section 5.1](#) for more details).
with SELECT/EXAMINE/STATUS.
If UIDVALIDITY value returned by the server differs,
the client MUST

- * empty the local cache of that mailbox;
- * "forget" the cached HIGHESTMODSEQ value for the mailbox;
- * remove any pending "actions" which refer to UIDs in that mailbox;
- * skip steps 1b and 2-II;

1b) Check the mailbox HIGHESTMODSEQ. If the cached value is the same as the one returned by the server, skip fetching message flags on step 2-II (i.e. the client only has to find out which messages got expunged).

2) Fetch the current "descriptors";

I) Discover new messages.

II) Discover changes to old messages using
"FETCH 1:* (FLAGS) (CHANGEDSINCE <cached-value>)" or
"SEARCH MODSEQ <cached-value>".

3) Fetch the bodies of any "interesting" messages that the client doesn't already have.

Example (HIGHESTMODSEQ value changed on the server while offline):

```
C: A142 SELECT INBOX
S: * 172 EXISTS
S: * 1 RECENT
S: * OK [UNSEEN 12] Message 12 is first unseen
S: * OK [UIDVALIDITY 3857529045] UIDs valid
S: * FLAGS (\Answered \Flagged \Deleted \Seen \Draft)
S: * OK [PERMANENTFLAGS (\Deleted \Seen \*)] Limited
S: * OK [HIGHESTMODSEQ 20010715194045007]
S: A142 OK [READ-WRITE] SELECT completed
```

after that either:

```
C: A143 UID FETCH 1:* (FLAGS) (CHANGEDSINCE 20010715194032001)
S: * 2 FETCH (UID 6 MODSEQ (20010715205008000) FLAGS (\Deleted))
S: * 5 FETCH (UID 9 MODSEQ (20010715195517000) FLAGS ($NoJunk
    $AutoJunk $MDNSent))
...
S: A143 OK FETCH completed
```

or:

```
C: A143 SEARCH MODSEQ 20010715194032001
S: * SEARCH 2 5 6 7 11 12 18 19 20 23 (MODSEQ 20010917162500)
S: A143 OK Search complete
```

8. Security Considerations

Security considerations are not discussed in this memo.
