Route Optimization Scheme based on Path Control Header
draft-na-nemo-path-control-header-00

Status of this Memo

This document is an Internet-Draft and is in full conformance with all provisions of [Section 10 of RFC2026](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF), its areas, and its working groups. Note that other groups may also distribute working documents as Internet-Drafts.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

The list of current Internet-Drafts can be accessed at <http://www.ietf.org/ietf/lid-abstracts.txt>

The list of Internet-Draft Shadow Directories can be accessed at <http://www.ietf.org/shadow.html>.

Abstract

In this memo, we propose a unified Route Optimization (RO) scheme that can solve several types of RO problem by using Path Control Header (PCH) Piggybacking. In our scheme, Home Agent (HA) can piggyback the PCH on the packet which is reversely forwarded to Mobile Router (MR). That enables any PCH-aware routing facilities.

Internet Draft

Path Control Header

Apr

the route to make a R0 tunnel with MR using the Care-of address of the MR contained in the PCH. By applying to some already known problems, we show that our scheme can incrementally optimize routes via default HA-MR tunnel through the simple PCH interpretation.

1. Introduction

NEMO Basic Support Solution[15] would suppose to support transparent mobility to mobile network nodes(MNNs) in mobile networks by using MR-HA bi-directional tunneling. However, inherently due to the use of the bi-directional tunnel, there are some types of route optimization problem [14] that need our attention. Until now, one solution is proposed to solve only one type of route optimization problem such as nested tunnel optimization.

In this memo, we propose a route optimization scheme based on PCH(Path Control Header) piggybacking by HA. The scheme is a unified solution that can solve several types of route optimization problem with applying the same principle to the routing facilities such as HA, MR and Correspondent Router(CN).

In the proposed scheme, HA does piggyback PCH on the packet that is reversely forwarded from MR through bi-directional MR-HA tunnel. PCH is a hop-by-hop option header so that it can be processed by all of the routing facilities on the path that is from HA to CN. HA forwards the packet with PCH to CN for the route optimization. The router on the path makes a RO(Route Optimization) tunnel between MR and itself using the information which is the CoA of MR that is contained in PCH.

This memo describes how we can apply PCH based scheme on two

problem spaces listed in [14]. One is to CR based route optimization in routing infrastructure and the other is to nested tunnels optimization for which many of solutions in have been proposed. The basic operation and signaling will detailed in [section 3](#) and 4.

Our proposed RO scheme, PCH piggybacking by HA, is a simple effective one in solving the problems of route optimization network mobility support. By taking the functional extension routing facilities such as HA, MR and CR, we can dynamically incrementally optimize the routes over CN-HA-MR without the transparency to CN.

We expect that the basic concept of this scheme can be used support other mobility-related route optimizations as a unified solution, not limited to network mobility.

[2](#). Terminology

It is assumed that readers are familiar with NEMO terminology described in [2][14], and the terms described in [4][5]. In addition, we define a few of terms used in describing the operation of our solution.

Path Control Header (PCH)

IPv6 hop-by-hop option header piggybacked on the reverse forwarded packet by HA for the route optimization. The header contains, as an option data, a form of array of global addresses that are the addresses of Mobile Router along the nested path which means from TLMR to any nested mobile networks.

RO Tunnel (ROT)

Any tunnel that created by the scheme of route optimization proposed by this document is referred to a "RO Tunnel".

Nested RO Tunnel (NROT)

Any RO tunnel that do require the source routing using Routing Header Type 0 (RH0). This kind of RO tunnel is used in optimizing the nested tunnels to guarantee the correct routing over nested MRs.

Correspondent Router (CR)

Any router in the Internet that can play a role of a correspondent agent for a set of correspondent nodes maybe an access router serving the routing service to a set of subnets or a border router located in AS-level or inter-AS level.

Path Control Header

Apr

[3. Basic Operations](#)

[3.1 PCH Piggybacking by HA](#)

To route optimization, HA does piggyback PCH on the packet reversely forwarded from MR through bi-directional MR-HA tunnel. PCH is a hop-by-hop option header so that it can be processed by all of the routing facilities on the path that is from HA to MR. The mentioned routing facility means an entity which can play the role of transparent correspondent agent. The router in the Internet that implements such a function of transparent correspondent agent we call it a CR, provides the packet redirection service to the correspondent nodes behind it by intercepting the packets sent from them.

redirecting to the R0 tunnel. The R0 tunnel between CR and MR can be established when CR gets know the existence of HA by processing the packet with PCH.

In fig.1, HA de-capsulates the encapsulated packet forwarded by MR via MR-HA tunnel and then forwards the PCH piggybacked packet to CN for the route optimization. Any existing CR on the path from MR to CN can catch the path control information as examining the packet. Therefore, the CR can initiate the procedure of setting up R0 tunnel between itself and MR using the CoA of MR which is contained in PCH. After setting up R0 tunnel, the packets of MR will be redirected to R0 tunnel at CR.

Fig.1 PCH piggybacking by HA

This scheme is simple and effective in respects of R0. It only requires a little effort of HA to provide the R0 tunnel between MR and CR. HA does PCH piggybacking on the packet which taking the optimized path of MR-HA tunnel. In here, we can say that CR is an access router that providing the routing service for a few subnets or a border router that runs BGP routing protocol.

Fig.2 shows the structure of PCH. PCH has address information and option data. In here, the address information represents the list of IPv6 addresses. The address contained in PCH indicates the CoA of MR in MR-HA relationship. Through PCH, CR gets know the CoA of MR so that CR can initiate the signaling for R0 tunnel.

PCH(Path Control Header) : IPv6 Hop-by-Hop Options Header

Option Type : 00 0 XXXXX

00 - skip over this option and continue processing the next

0 - Option Data does not change en-route

XXXXX = Path Control Option ID (to be assigned by IANA)

Option Data :

```

+-----+-----+-----+-----+-----+
| Length(n) | Address(1) | Address(2) | . . . | Address(n) |
+-----+-----+-----+-----+-----+

```

Fig.2 Type and data format of PCH option

In fig.3 that shows the case of forming nested tunnels, PCHs contain two CoAs, each of MR1 and MR2. HA2 gets to know the fact that its MR2-HA2 tunnel is nested under outer MR1-HA1 tunnel after taking a look at the packet with PCH1. The nested HA just adds the CoA of its MR on the received PCH to make its PCH. In fig.3, HA2 does piggyback PCH which includes the CoA of MR1 (the exit point of the outer tunnel) and the CoA of MR2 (the exit point of its inner tunnel). In this case, one CR on the path between HA2 and CN will be able to make R0 tunnel with MR2 by using the nested information carried in PCH.

```

          +----+          +----+          +----+          +----+
CN <----| HA2 |=====| HA1 |////////| MR1 |=====| MR2 |<----
      \ +----+          \ +----+          +----+          +----+
      \                   \ PCH=[1|CoA of MR1]
      \                   PCH=[2|CoA of MR1, CoA of MR2]

```

Fig.3 Nested PCH piggybacking by HAs

3.2 Making a R0 Tunnel

The CR can make a R0 tunnel after getting the piggybacked PCH from HA. The signaling to construct a R0 tunnel between CR and MR is done with 3-way handshake as in fig.4. The messages defined in this section are carried by Mobility Header (MIPv6). We define new messages: BR (Binding Request) to notify MR of the need of R0 tunnel, BU (Binding Update) and BA (Binding Acknowledgement) are same as defined in MIPv6 and NEMO. Additionally, we define new mobility option to carry a set of network prefixes. CR can use this option to inform MR of the routing information of networks which are reachable from R0 tunnel. By referring those of routing information, MR reversely forwards the packets to pre-established R0 tunnel.

because they are destined to the network that is reachable tunnel.
CR does the same thing for the prefix of mobile network that bound through BU from MR. CR intercepts the packets destined prefix and redirects them to pre-established R0 tunnel.

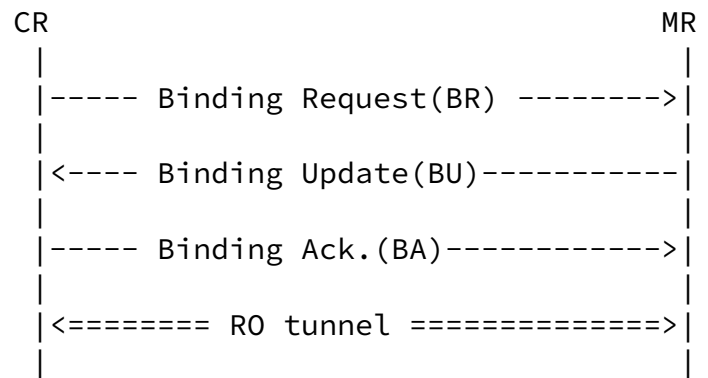

Fig.4 The signaling procedure for R0 Tunnel

4. Route Optimization

4.1 Route Optimization by CR

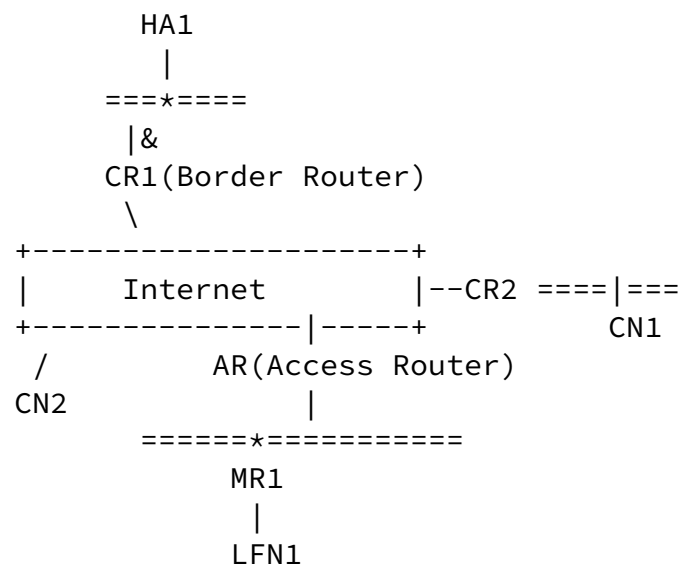

Fig.5 CR-based Route Optimization : Network Configuration

As in fig.5 and 6, CR1 and CR2 can simultaneously establish a tunnel with MR through one PCH piggybacking by HA1. This is possible because both are on the path that is from HA1 to CN1. In that case, the packets sent from CNs in all of subnets attached to CR2 are redirected to the R0 tunnel at CR2. CR1 can serve the packets sent from any CNs (in here, CN2) that are scattered in the Internet. The packets reached on CR1 indicate that there is no CR in the path that is from CN2 to CR1, or CR but still not received PCH. The packets from CN2 are redirected at CR1 and reversely the packets from MR1 are forwarded via HA1. At next time, the CR on the path can make a R0 tunnel by picking PCH up on the reverse path. The forwarded packets from HA1. As a result of PCH piggybacking, we can serve the incremental route optimization to all of CNs.

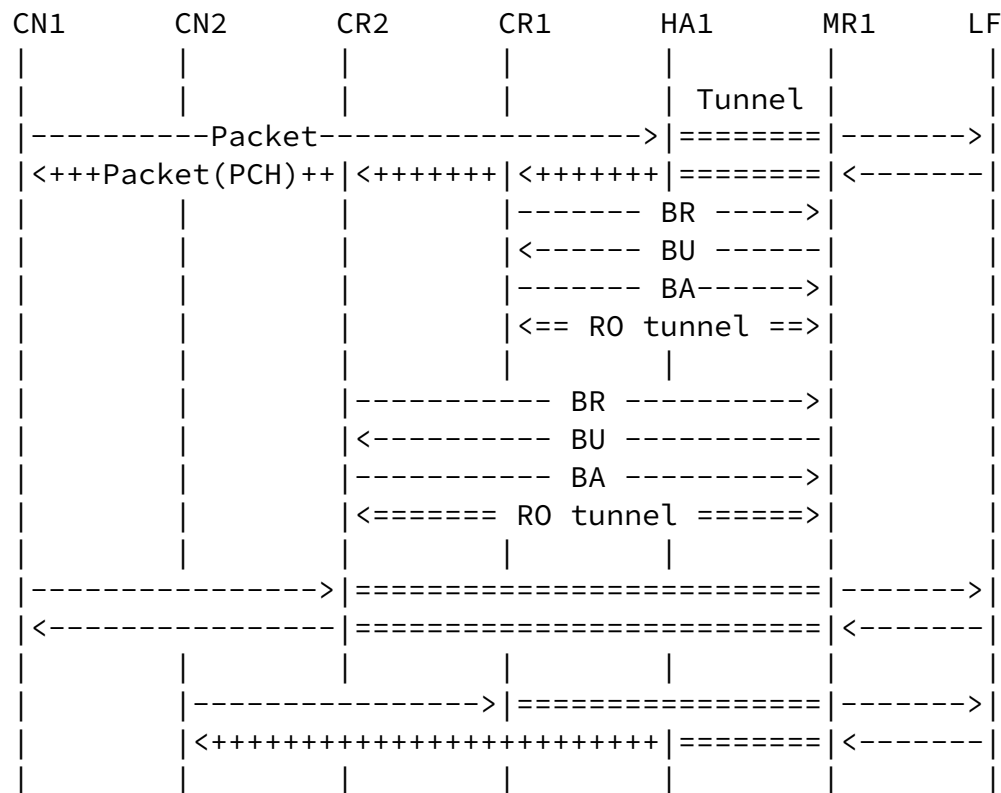

Fig.6 CR-based Route Optimization : Message Flow

[4.2](#) Route Optimization over MR-to-MR

As in fig.7 and fig.8, we can get the R0 tunnel over MR-to-MR using PCH piggybacking. MR per se interprets PCH piggybacked by the HA of the other MR and initiates the signaling for R0 tunnel with the other MR. As a result of that, the nodes behind one MR can directly communicate with the nodes behind the other MR without

routing overhead.

Apr

Fig.7 MR-to-MR Route Optimization : Network Configuration

Fig.9 and 10 show the network configuration and message flow for the nested tunnels optimization using PCH piggybacking. In mobile networks, R0 tunnel is called Nested R0 Tunnel (NR0T) because we introduce the source routing concept in handling nested tunnel optimization. To the correct routing in the network configuration, we take advantage of IPv6 Routing Header Type 0 (RH0) in NR0T.

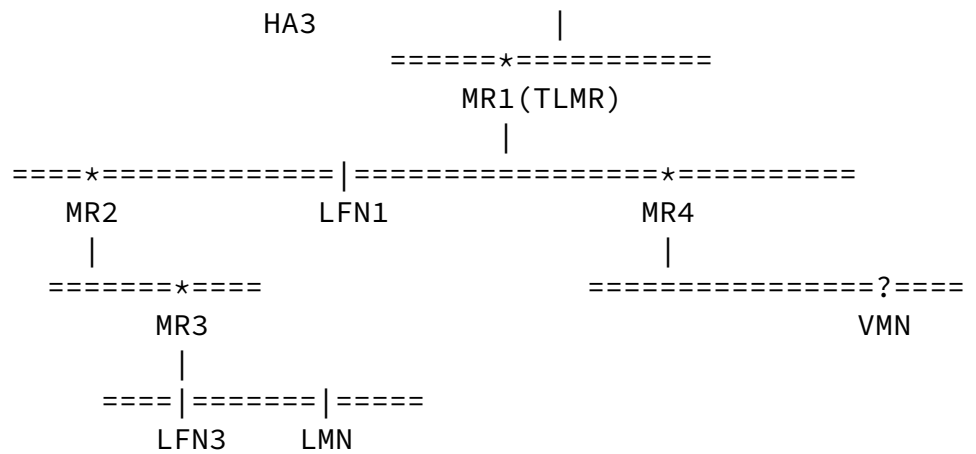

Fig.9 Nested Tunnels Optimization : Network Configuration

In fig.10, CR gets know the existence of nested tunnels through the information (MR1's CoA and MR2's CoA, MR3's CoA) and then initiates the signaling for NROT to MR3 via nested tunnels. At this time, the Binding Request(BR) message contains Nested Routing Path Option(NRP Option). NRP Option is used to inform MR3 of the nested path information. If MR3 receives BR message having NRP option, MR3 gets know that it is nested. Therefore, the tunnel between MR3 becomes a NROT.

In NROT, the entry point of tunnel adds RH0 at encapsulation. Reversely, the exit point of tunnel deletes RH0 at decapsulation.

For the packets tunneled from CR to MR3, the packet forwarding is done with source routing of RH0 (MR1->MR2->MR3). For the packets tunneled from MR3 to CR, the reverse source routing (MR2->MR1->CR) occurs. Fig.11 and 12 shows the content of RH0 at the packet delivery.

5. Extensions

The proposed scheme requires some extensions for existing M NEMO Basic Support protocols.

5.1 MIPv6 Extension

The proposed scheme requires some extensions for existing MIP protocol [1]. As you see in [section 3.2](#), new mobility message is required. And also, new two mobility options are needed. describe the purpose and usage of them in here.

Binding Request Message (BR Message): This message is used to notify MR of the need of R0 tunnel. If the sender of this message detects the nested tunneling (i.e. PCH contains O addresses), it should put NRP (Nested Routing Path) Option in this message to inform MR of its nested path information. Otherwise, this message includes no special information for triggering the signaling of R0 tunnel.

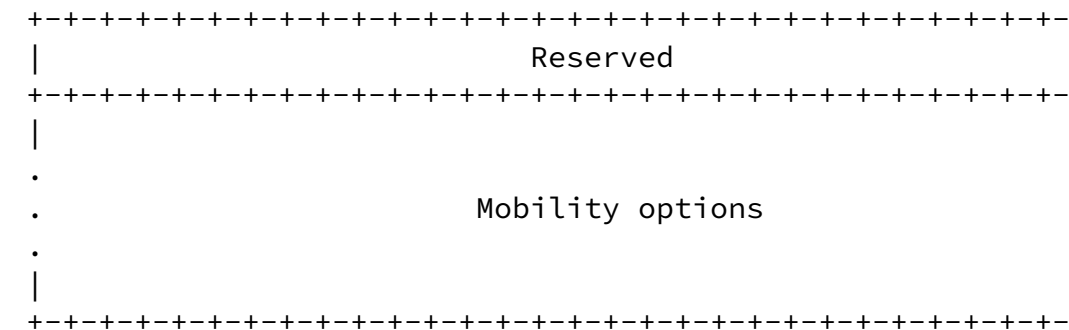

Nested Routing Path Option (NRP Option): The initiator of signaling of RO tunnel should add this mobility option in the message to set up the Nested RO Tunnel with nested MR. This option contains the list of addresses that represents the topology of nested MRs. That is used for MR to assign the routing path that is necessary to nested tunnels optimization.

Reachable Network Prefixes Option (RNP Option): This option is used to let MR know about the network prefixes which are reachable via R0 tunnel. By using this information associated with R0 tunnel, MR can select the optimized path (i.e. R0) for the out-going packets. This option should be contained in the R0 message.

5.1.1 Binding Request Message (BR Message)

New BR Message is defined to notify MR of the need of RO tu
sender detects the nested mobility, it has to put NRP Optio
in this message to inform MR of its nested path information
format of this message is as follows:

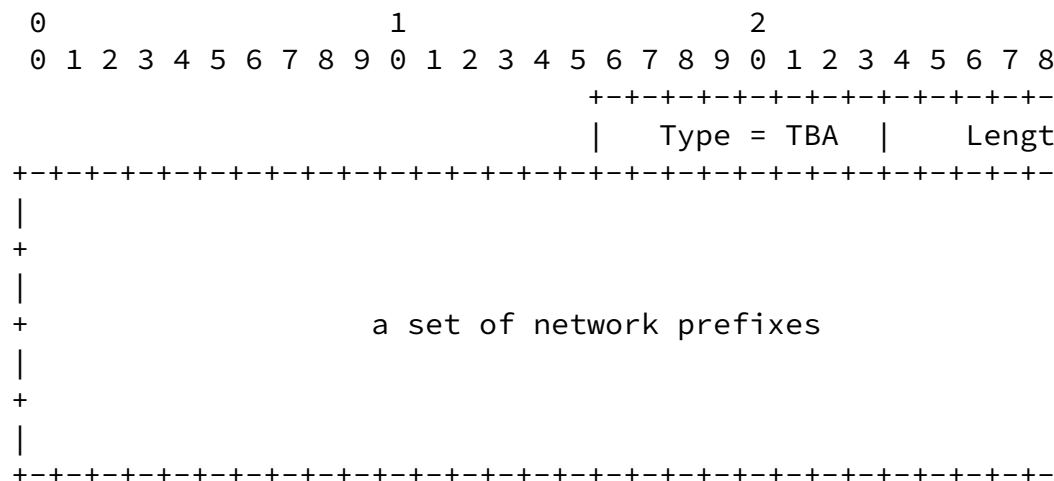

[illegible]

TBD

5.1.2 Reachable Network Prefixes Option (RNP Option)

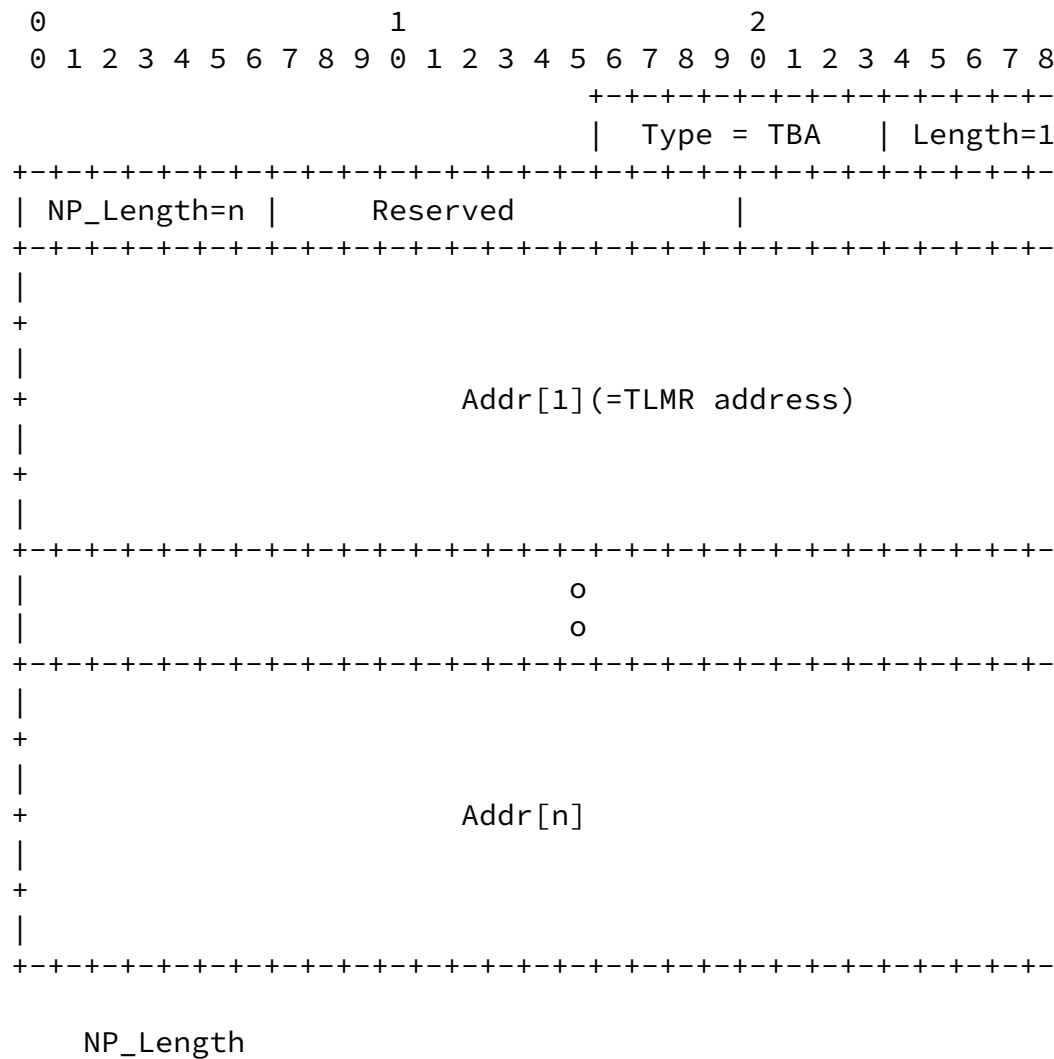

RNP Option is used to let MR know about the networks reachable through the tunnel. By using this information associated with the tunnel between CR and MR, MR can select the optimized path for the outgoing packets. This option should be contained either in the BR or in the message for the route optimization in the reverse packet direction. The format of this option is as follows:

TBD

5.1.3 Nested Routing Path Option (NRP Option)

CR adds new mobility option, NRP Option in BR message to set up a Nested R0 Tunnel with nested MR. The format of this option follows:

8-bit unsigned integer that indicates the number of slots.

Addr[1..n]

Vector of IPv6 global addresses of MRs on the nested path numbered 1 to n.

NRP Option is only valid in a Binding Request message. The purpose of this option is to inform MR that it can do optimize the tunnels overhead. Using this information, MR can route packets

Na, et al.

Expires - November 2004

[P

Internet Draft

Path Control Header

Apr

CR via the MRs on the nested path by using type 0 RH option header.

[5.2](#) MR Extension

For route optimization, MR MUST understand BR message sent to routing facilities such as CR. According to MIPv6 Spec.[\[1\]](#), maintain Binding Update List(BU List). In managing BU List, following information MUST be maintained additionally to use tunnel defined in this proposed solution.

RO Tunnel (ROT) flag: When it is set, it indicates that the associated BU entry is for ROT tunnel. All of ROT tunnels contain a set of network prefixes that is carried from RNP Option.

Nested RO Tunnel (NROT) flag: When it is set, it indicates the associated BU entry is for NROT tunnel. In this case, the entry should contain the nested path information carried by NRP Option.

Nested Path Information (NPI) Vector: The address vector information is transferred in NRP Option. This information is only valid when NROT flag is set.

Network Prefixes (NP) Vector: The address vector information is transferred in RNP Option. This information is only valid when either ROT flag or NROT flag is set.

The successful establishment of RO tunnel allows the ready-to-use enabled tunnel interface that would be associated with the

correspondent entry of BU List. That tunnel interface should be setup to add IPv6 RH0(Routing Header Type 0) optional header encapsulation of tunneled packets if the NROT flag is set.

Lastly, MR should maintain the R0 tunnels in its own context. In other words, MR can tear down less necessary R0 tunnels according to its own criterion such as Least Recently Used(LRU) in case of the resource shortage.

[5.3](#) HA Extension

For route optimization, HA should maintain the state of PCH piggybacking for per traffic flow. The traffic flow can be classified by the destination address of the packets. HA does not piggyback PCH on one packet per the traffic flow. The piggybacking state should be managed by soft-state. The piggybacking state

Na, et al.

Expires - November 2004

[P

Internet Draft

Path Control Header

Apr

per traffic flow becomes set when the first packet is piggybacked and reset when the state timer is expired. HA doesn't need to piggyback PCH on the packets belong to the traffic flow while the correspondent state is set. The overhead of managing the piggybacking state can be minimized by the careful implementation.

According to MIPv6 Spec.[\[1\]](#), HA MUST maintain Binding Cache. Like MR extension. Additionally, HA manages the following information in associated BC entry for route optimization.

Route Optimization (R0) flag: When it is set, it indicates that the associated BU entry is R0 enabled. R0 may be enabled or disabled by administrative means.

Piggybacking State Table (PST): An entry of this table represents a record that contains (flow-id = destination address, time-info = UTC time). It indicates that the packet belong to the traffic flow(=flow-id) was piggybacked with PCH at time(=time-info).

For the packets forwarded via R0 enabled tunnel from MR, HA decapsulates them, and checks the need of PCH piggybacking. If there is an entry that contains the destination address of the packet in the PST, PCH is not piggybacked to the packet at forwarding. Otherwise, HA creates new entry in PST for that traffic flow and piggybacks

PCH on the packet at forwarding. We can use one global time delete the records which were long sustained in PST.

6. Security Considerations

TBD

In particular, considering security concerns is very important when applying the Internet protocol. At this moment, Public Key Infrastructure (PKI) can be a solution to support the integrity of the origin-authentication of PCH because the participants in the scheme are limited to some of routing facilities. We know the potential security problem of our scheme must be deeply considered. We leave the detailed security consideration into the future item with high priority.
