Abstract

This document describes an extension to DNS Over HTTPS (DoH) that allows hiding client IP addresses via proxying encrypted DNS transactions. This improves privacy of DNS operations by not allowing any one server entity to be aware of both the client IP address and the content of DNS queries and answers.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at https://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on 30 July 2021.

1. Introduction

DNS Over HTTPS (DoH) [RFC8484] defines a mechanism to allow DNS messages to be transmitted in encrypted HTTP messages. This provides improved confidentiality and authentication for DNS interactions in various circumstances.
While DoH can prevent eavesdroppers from directly reading the contents of DNS exchanges, clients cannot send DNS queries and receive answers from servers without revealing their local IP address, and thus information about the identity or location of the client.

Proposals such as Oblivious DNS ([I-D.annee-dprive-oblivious-dns]) increase privacy by ensuring no single DNS server is aware of both the client IP address and the message contents.

This document defines Oblivious DoH, an extension to DoH that permits proxied resolution, in which DNS messages are encrypted so that no DoH server can independently read both the client IP address and the DNS message contents.

This mechanism is intended to be used as one option for resolving privacy-sensitive content in the broader context of Adaptive DNS [I-D.pauly-dprive-adaptive-dns-privacy].

1.1. Specification of Requirements

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.

2. Terminology

This document defines the following terms:

Oblivious Server: A DoH server that acts as either an Oblivious Proxy or Oblivious Target.

Oblivious Proxy: An Oblivious Server that proxies encrypted DNS queries and responses between a client and an Oblivious Target.

Oblivious Target: An Oblivious Server that receives and decrypts encrypted client DNS queries from an Oblivious Proxy, and returns encrypted DNS responses via that same Proxy. In order to provide DNS responses, the Target can be a DNS resolver, be co-located with a resolver, or forward to a resolver.
Throughout the rest of this document, we use the terms Proxy and Target to refer to an Oblivious Proxy and Oblivious Target, respectively.

3. Deployment Requirements

Oblivious DoH requires, at a minimum:

* Two Oblivious Servers, where one can act as a Proxy, and the other can act as a Target.

* Public keys for encrypting DNS queries that are passed from a client through a Proxy to a Target (Section 6). These keys guarantee that only the intended Target can decrypt client queries.

The mechanism for discovering and provisioning the DoH URI Templates and public keys is via parameters added to DNS resource records. The mechanism for discovering the public key is described in Section 5. The mechanism for discovering a DoH URI Template is described in [I-D.pauly-add-resolver-discovery].

4. HTTP Exchange

Unlike direct resolution, oblivious hostname resolution over DoH involves three parties:

1. The Client, which generates queries.

2. The Proxy, which receives encrypted queries from the client and passes them on to a Target.

3. The Target, which receives proxied queries from the client via the Proxy and produces proxied answers.

--- [ Request encrypted with target public key ] -->
+----------+-----------------+-----------------+
| Client   | Oblivious Proxy | Oblivious Target |
+----------+-----------------+-----------------+
4.1. HTTP Request

Oblivious DoH queries are created by the Client, and sent to the Proxy. Requests to the Proxy indicate which DoH server to use as a Target by specifying two variables: "targethost", which indicates the host name of the Target server, and "targetpath", which indicates the path on which the Target's DoH server is running. See Section 4.2 for an example request.

Oblivious DoH messages have no cache value since both requests and responses are encrypted using ephemeral key material. Clients SHOULD prefer using HTTP methods and headers that will prevent unhelpful cache storage of these exchanges (i.e., preferring POST instead of GET).

4.2. HTTP Request Example

The following example shows how a client requests that a Proxy, "dnsproxy.example.net", forwards an encrypted message to "dnstarget.example.net". The URI template for the Proxy is "https://dnsproxy.example.net/dns-query?targethost,targetpath". The URI template for the Target is "https://dnstarget.example.net/dns-query".
4.3. HTTP Response

The response to an Oblivious DoH query is generated by the Target. It MUST set the Content-Type HTTP header to "application/oblivious-dns-message" for all successful responses. The body of the response contains an encrypted DNS message; see Section 7.

The response from a Target MUST set the Content-Type HTTP header to "application/oblivious-dns-message" which MUST be forwarded by the Proxy to the Client. A Client MUST only consider a response which contains the Content-Type header in the response before processing the payload. A response without the appropriate header MUST be treated as an error and be handled appropriately. All other aspects of the HTTP response and error handling are inherited from standard DoH.
Proxies MUST forward responses unmodified to clients. Specifically, the HTTP status code generated by Targets must be forwarded to clients unmodified.

4.4. HTTP Response Example

The following example shows a 2xx (Successful) response that can be sent from a Target to a client via a Proxy.

```plaintext
:status = 200
ccontent-type = application/oblivious-dns-message
ccontent-length = 154

(Bytes containing the encrypted payload for an Oblivious DNS response)
```

Requests that cannot be processed by the target result in 4xx (Client Error) responses. If the target and client keys do not match, it is an authorization failure (HTTP status code 401; see Section 3.1 of [RFC7235]). Otherwise, if the client's request is invalid, such as in the case of decryption failure, wrong message type, or deserialization failure, this is a bad request (HTTP status code 400; see Section 6.5.1 of [RFC7231]).

Even in case of DNS responses indicating failure, such as SERVFAIL or NXDOMAIN, a successful HTTP response with a 2xx status code is used as long as the DNS response is valid. This is similar to how DoH [RFC8484] handles HTTP response codes.

In case of server error, the usual HTTP status code 500 (see Section 6.6.1 of [RFC7231]) applies.

5. Configuration and Public Key Discovery

In order to use a DoH server as a Target, the client must know a public key to use for encrypting its queries. This document specifies one discovery mechanism for public keys using the SVCB or HTTPSSVC record type ([I-D.ietf-dnsop-svcb-https]) for a name owned by the server.
The Service Binding key name is "odohconfig" (Section 12). If present, this key/value pair contains the public key to use when encrypting Oblivious DoH messages that will be targeted at a DoH server. The format of the key is defined in (Section 6).

Clients that use this discovery mechanism MUST only use keys that were retrieved from records protected by DNSSEC [RFC4033] to encrypt messages to a Target.

Servers SHOULD rotate public keys regularly. It is RECOMMENDED that servers rotate keys every day. Shorter rotation windows reduce the anonymity set of clients that might use the public key, whereas longer rotation windows widen the timeframe of possible compromise.

6. Configuration and Public Key Format

An Oblivious DNS public key configuration is a structure encoded, using TLS-style encoding [RFC8446], as follows:

```
struct {
    uint16 kem_id;
    uint16 kdf_id;
    uint16 aead_id;
    opaque public_key<1..2^16-1>;
} ObliviousDoHConfigContents;

struct {
    uint16 version;
    uint16 length;
    select (ObliviousDoHConfig.version) {
        case 0xff04: ObliviousDoHConfigContents contents;
    }
} ObliviousDoHConfig;

ObliviousDoHConfig ObliviousDoHConfigs<1..2^16-1>;
```

The "ObliviousDoHConfigs" structure contains one or more "ObliviousDoHConfig" structures in decreasing order of preference. This allows a server to support multiple versions of Oblivious DoH and multiple sets of Oblivious DoH parameters.
Oblivious DoH configuration, with the following fields.

version The version of Oblivious DoH for which this configuration is used. Clients MUST ignore any "ObliviousDoHConfig" structure with a version they do not support. The version of Oblivious DoH specified in this document is "0xff04".

length The length, in bytes, of the next field.

contents An opaque byte string whose contents depend on the version. For this specification, the contents are an "ObliviousDoHConfigContents" structure.

An "ObliviousDoHConfigContents" contains the information needed to encrypt a message under "ObliviousDoHConfigContents.public_key" such that only the owner of the corresponding private key can decrypt the message. The values for "ObliviousDoHConfigContents.kem_id", "ObliviousDoHConfigContents.kdf_id", and "ObliviousDoHConfigContents.aead_id" are described in [I-D.irtf-cfrg-hpke] Section 7. The fields in this structure are as follows:

kem_id The HPKE KEM identifier corresponding to "public_key". Clients MUST ignore any "ObliviousDoHConfig" structure with a key using a KEM they do not support.

kdf_id The HPKE KDF identifier corresponding to "public_key". Clients MUST ignore any "ObliviousDoHConfig" structure with a key using a KDF they do not support.

aead_id The HPKE AEAD identifier corresponding to "public_key". Clients MUST ignore any "ObliviousDoHConfig" structure with a key using an AEAD they do not support.

public_key The HPKE public key used by the client to encrypt Oblivious DoH queries.

7. Protocol Encoding

7.1. Message Format

There are two types of Oblivious DoH messages: Queries (0x01) and Responses (0x02). Both messages carry the following information:

1. A DNS message, which is either a Query or Response, depending on context.
2. Padding of arbitrary length which MUST contain all zeros.

They are encoded using the following structure:

```c
struct {
    opaque dns_message<1..2^16-1>;
    opaque padding<0..2^16-1>;
} ObliviousDoHMessagePlaintext;
```

Both Query and Response messages use the "ObliviousDoHMessagePlaintext" format.

```
ObliviousDoHMessagePlaintext ObliviousDoHQuery;
ObliviousDoHMessagePlaintext ObliviousDoHResponse;
```

An encrypted "ObliviousDoHMessagePlaintext" is carried in a "ObliviousDoHMessage" message, encoded as follows:

```c
struct {
    uint8  message_type;
    opaque key_id<0..2^16-1>;
    opaque encrypted_message<1..2^16-1>;
} ObliviousDoHMessage;
```

The "ObliviousDoHMessage" structure contains the following fields:

- **message_type** A one-byte identifier for the type of message. Query messages use "message_type" 0x01, and Response messages use "message_type" 0x02.

- **key_id** The identifier of the corresponding "ObliviousDoHConfigContents" key. This is computed as "Expand(Extract("", config), "odoh key id", Nh)", where "config" is the ObliviousDoHConfigContents structure and "Extract", "Expand", and "Nh" are as specified by the HPKE cipher suite KDF corresponding to "config.kdf_id".

- **encrypted_message** An encrypted message for the Oblivious Target (for Query messages) or client (for Response messages). Implementations MAY enforce limits on the size of this field depending on the size of plaintext DNS messages. (DNS queries, for example, will not reach the size limit of 2^16-1 in practice.)

The contents of "ObliviousDoHMessage.encrypted_message" depend on "ObliviousDoHMessage.message_type". In particular, "ObliviousDoHMessage.encrypted_message" is an encryption of a
7.2. Encryption and Decryption Routines

Clients use the following utility functions for encrypting a Query and decrypting a Response as described in Section 8.

crypt_query_body: Encrypt an Oblivious DoH query.

```python
def encrypt_query_body(pkR, key_id, Q_plain):
    enc, context = SetupBaseS(pkR, "odoh query")
    aad = 0x01 || len(key_id) || key_id
    ct = context.Seal(aad, Q_plain)
    Q_encrypted = enc || ct
    return Q_encrypted
```

decrypt_response_body: Decrypt an Oblivious DoH response.

```python
def decrypt_response_body(context, Q_plain, R_encrypted):
    key, nonce = derive_secrets(context, Q_plain)
    aad = 0x02 || 0x0000 // 0x0000 represents a 0-length KeyId
    R_plain, error = Open(key, nonce, aad, R_encrypted)
    return R_plain, error
```

The "derive_secrets" function is described below.

Targets use the following utility functions in processing queries and producing responses as described in Section 9.

setup_query_context: Set up an HPKE context used for decrypting an Oblivious DoH query.

```python
def setup_query_context(skR, key_id, Q_encrypted):
    enc || ct = Q_encrypted
    context = SetupBaseR(enc, skR, "odoh query")
    return context
```

decrypt_query_body: Decrypt an Oblivious DoH query.

```python
def decrypt_query_body(context, key_id, Q_encrypted):
    aad = 0x01 || len(key_id) || key_id
```
enc || ct = Q_encrypted
Q_plain, error = context.Open(aad, ct)
return Q_plain, error

derive_secrets: Derive keying material used for encrypting an Oblivious DoH response.

def derive_secrets(context, Q_plain):
    odoh_secret = context.Export("odoh secret", 32)
    odoh_prk = Extract(Q_plain, odoh_secret)
    key = Expand(odoh_prk, "odoh key", Nk)
    nonce = Expand(odoh_prk, "odoh nonce", Nn)
    return key, nonce

def encrypt_response_body(R_plain, answer_key, answer_nonce):
    aad = 0x02 || 0x0000 // 0x0000 represents a 0-length KeyId
    R_encrypted = Seal(answer_key, answer_nonce, aad, R_plain)
    return R_encrypted

8. Oblivious Client Behavior

Let "M" be a DNS message (query) a client wishes to protect with Oblivious DoH. When sending an Oblivious DoH Query for resolving "M" to an Oblivious Target with "ObliviousDoHConfigContents" "config", a client does the following:

1. Create an "ObliviousDoHQuery" structure, carrying the message M and padding, to produce Q_plain.

2. Deserialize "config.public_key" to produce a public key pkR of type "config.kem_id".

3. Compute the encrypted message as "Q_encrypted = encrypt_query_body(pkR, key_id, Q_plain)", where "key_id" is as computed in Section 7. Note also that "len(key_id)" outputs the length of "key_id" as a two-byte unsigned integer.
4. Output a ObliviousDoHMessage message "Q" where "Q.message_type = 0x01", "Q.key_id" carries "key_id", and "Q.encrypted_message = Q_encrypted".

The client then sends "Q" to the Proxy according to Section 4.1. Once the client receives a response "R", encrypted as specified in Section 9, it uses "decrypt_response_body" to decrypt "R.encrypted_message" and produce R_plain. Clients MUST validate "R_plain.padding" (as all zeros) before using R_plain.dns_message.

9. Oblivious Target Behavior

Targets that receive a Query message Q decrypt and process it as follows:

1. Look up the "ObliviousDoHConfigContents" according to "Q.key_id". If no such key exists, the Target MAY discard the query, and if so, it MUST return a 400 (Client Error) response to the Proxy. Otherwise, let "skR" be the private key corresponding to this public key, or one chosen for trial decryption.

2. Compute "context = setup_query_context(skR, Q.key_id, Q.encrypted_message)".

3. Compute "Q_plain, error = decrypt_query_body(context, Q.key_id, Q.encrypted_message)".

4. If no error was returned, and "Q_plain.padding" is valid (all zeros), resolve "Q_plain.dns_message" as needed, yielding a DNS message M. Otherwise, if an error was returned or the padding was invalid, return a 400 (Client Error) response to the Proxy.

5. Create an "ObliviousDoHResponseBody" structure, carrying the message "M" and padding, to produce "R_plain".

6. Compute "answer_key, answer_nonce = derive_secrets(context, Q_plain)".

7. Compute "R_encrypted = encrypt_response_body(R_plain, answer_key, answer_nonce)". The "key_id" field used for encryption is empty,
yielding "0x0000" as part of the AAD. Also, the "Seal" function is that which is associated with the HPKE AEAD.

8. Output a "ObliviousDoHMessage" message "R" where "R.message_type = 0x02", "R.key_id = nil", and "R.encrypted_message = R_encrypted".

The Target then sends "R" in a 2xx (Successful) response to the Proxy; see Section 4.3. The Proxy forwards the message "R" without modification back to the client as the HTTP response to the client's original HTTP request. In the event of an error (non 2xx status code), the Proxy forwards the Target error to the client; see Section 4.3.

10. Compliance Requirements

Oblivious DoH uses draft-07 of HPKE for public key encryption [I-D.irtf-cfrg-hpke]. In the absence of an application profile standard specifying otherwise, a compliant Oblivious DoH implementation MUST support the following HPKE cipher suite:

* KEM: DHKEM(X25519, HKDF-SHA256) (see [I-D.irtf-cfrg-hpke], Section 7.1)
* KDF: HKDF-SHA256 (see [I-D.irtf-cfrg-hpke], Section 7.2)
* AEAD: AES-128-GCM (see [I-D.irtf-cfrg-hpke], Section 7.3)

11. Security Considerations

DISCLAIMER: this is a work in progress draft and has not yet seen significant security analysis.

Oblivious DoH aims to keep knowledge of the true query origin and its contents known to only clients. As a simplified model, consider a case where there exists two clients C1 and C2, one proxy P, and one target T. Oblivious DoH assumes an extended Dolev-Yao style attacker which can observe all network activity and can adaptively compromise either P or T, but not C1 or C2. Once compromised, the attacker has access to all session information and private key material. (This generalizes to arbitrarily many clients, proxies, and targets, with the constraints that not all targets and proxies are simultaneously
compromised, and at least two clients are left uncompromised.) The attacker is prohibited from sending client identifying information, such as IP addresses, to targets. (This would allow the attacker to trivially link a query to the corresponding client.)

In this model, both C1 and C2 send an Oblivious DoH queries Q1 and Q2, respectively, through P to T, and T provides answers A1 and A2. The attacker aims to link C1 to (Q1, A1) and C2 to (Q2, A2), respectively. The attacker succeeds if this linkability is possible without any additional interaction. (For example, if T is compromised, it may return a DNS answer corresponding to an entity it controls, and then observe the subsequent connection from a client, learning its identity in the process. Such attacks are out of scope for this model.)

Oblivious DoH security prevents such linkability. Informally, this means:

1. Queries and answers are known only to clients and targets in possession of the corresponding response key and HPKE keying material. In particular, proxies know the origin and destination of an oblivious query, yet do not know the plaintext query. Likewise, targets know only the oblivious query origin, i.e., the proxy, and the plaintext query. Only the client knows both the plaintext query contents and destination.

2. Target resolvers cannot link queries from the same client in the absence of unique per-client keys.

Traffic analysis mitigations are outside the scope of this document. In particular, this document does not recommend padding lengths for ObliviousDoHQuery and ObliviousDoHResponse messages. Implementations SHOULD follow the guidance for choosing padding length in [RFC8467].

Oblivious DoH security does not depend on proxy and target indistinguishability. Specifically, an on-path attacker could determine whether a connection a specific endpoint is used for oblivious or direct DoH queries. However, this has no effect on confidentiality goals listed above.
11.1. Denial of Service

Malicious clients (or proxies) may send bogus Oblivious DoH queries to targets as a Denial-of-Service (DoS) attack. Target servers may throttle processing requests if such an event occurs. Additionally, since Targets provide explicit errors upon decryption failure, i.e., if ciphertext decryption fails or if the plaintext DNS message is malformed, Proxies may throttle specific clients in response to these errors.

Malicious Targets or Proxies may send bogus answers in response to Oblivious DoH queries. Response decryption failure is a signal that either the proxy or target is misbehaving. Clients can choose to stop using one or both of these servers in the event of such failure. However, as above, malicious Targets and Proxies are out of scope for the threat model.

11.2. General Proxy Services

Using DoH over anonymizing proxy services such as Tor would also achieve the desired goal of separating query origins from their contents. However, there are several reasons why such systems are undesirable in comparison Oblivious DoH:

1. Tor is also meant as a generic connection-level anonymity system, and thus seems overly complex and costly for the purpose of proxying individual DoH queries. In contrast, Oblivious DoH is a lightweight extension to standard DoH, implemented as an application-layer proxy, that can be enabled as a default mode for users which need increased privacy.

2. As a one-hop proxy, Oblivious DoH encourages connection-less proxies to mitigate client query correlation with few round-trips. In contrast, multi-hop systems such as Tor often run secure connections (TLS) end-to-end, which means that DoH servers
could track queries over the same connection. Using a fresh DoH connection per query would incur a non-negligible penalty in connection setup time.

12. IANA Considerations

12.1. Oblivious DoH Message Media Type

This document registers a new media type, "application/oblivious-dns-message".

Type name: application

Subtype name: oblivious-dns-message

Required parameters: N/A

Optional parameters: N/A

Encoding considerations: This is a binary format, containing encrypted DNS requests and responses, as defined in this document.

Security considerations: See this document. The content is an encrypted DNS message, and not executable code.

Interoperability considerations: This document specifies format of conforming messages and the interpretation thereof.

Published specification: This document.

Applications that use this media type: This media type is intended to be used by clients wishing to hide their DNS queries when using DNS over HTTPS.

Additional information: None

Person and email address to contact for further information: See Authors' Addresses section

Intended usage: COMMON

Restrictions on usage: None

Author: IETF
This document adds a parameter ("odohconfig") to the "Service Binding (SVCB) Parameter" registry [I-D.ietf-dnsop-svcb-https]. The allocation request is 32769, taken from the to the First Come First Served range.

If present, the "odohconfig" parameter contains a ObliviousDoHConfigs structure. In wire format, the value of the parameter is an ObliviousDoHConfigs vector, including the redundant length prefix. In presentation format, the value is encoded in [base64].

Name: odohconfig

SvcParamKey: 32769

Meaning: An ObliviousDoHConfigs structure.

Reference: This document.

This work is inspired by Oblivious DNS [I-D.annee-dprive-oblivious-dns]. Thanks to all of the authors of that document. Thanks to Elliot Briggs, Marwan Fayed, Frederic Jacobs, Tommy Jensen Paul Schmitt, and Brian Swander for the feedback and input.
