Tunneling TCP inside QUIC draft-piraux-quic-tunnel-tcp-01

Abstract

This document specifies a new operating mode for a QUIC tunnel to efficiently convey TCP bytestreams.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of <u>BCP 78</u> and <u>BCP 79</u>.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <u>https://datatracker.ietf.org/drafts/current/</u>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on January 14, 2021.

1. Introduction

The recently proposed QUIC tunnel protocol [<u>I-D.piraux-quic-tunnel</u>] supports the exchange of IP packets or Ethernet frames over a QUIC connection. Its first operating mode, the datagram mode, transports plain packets inside QUIC frames. Its main advantage is that it supports any network-layer protocol. However, this advantage comes with a large per-packet overhead since each packet contains both a network and a transport header. All these headers must be transmitted in addition to the IP/UDP/QUIC headers of the QUIC connection. For TCP connections for instance, the per-packet overhead can be large.

In this document, we propose a new operating mode for the QUIC tunnel protocol, called the stream mode. It takes advantage of the QUIC streams to efficiently transport TCP bytestreams over a QUIC connection. <u>Section 3</u> describes this new mode. <u>Section 5</u> specifies the format of the messages introduced by this document. <u>Section 6</u> contains example flows.

<u>2</u>. Conventions and Definitions

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in <u>BCP</u> <u>14</u> [<u>RFC2119</u>] [<u>RFC8174</u>] when, and only when, they appear in all capitals, as shown here.

<u>3</u>. The stream mode

Since QUIC supports multiple streams, another possibility to carry the data exchanged over TCP connections between the client and the concentrator is to transport the bytestream of each TCP connection as one of the bidirectional streams of the QUIC connection. For this, we base our approach on the 0-RTT Convert protocol [<u>I-D.ietf-tcpm-converters</u>] that was proposed to ease the deployment of TCP extensions. In a nutshell, it is an application proxy that converts TCP connections, allowing the use of new TCP extensions through an intermediate relay.

We use a similar approach in our stream mode. When a client opens a stream, it sends at the beginning of the bytestream one or more TLV messages indicating the IP address and port number of the remote destination of the bytestream. Their format is detailed in section <u>Section 5.1</u>. Upon reception of such a TLV message, the concentrator opens a TCP connection towards the specified destination and connects the incoming bytestream of the QUIC connection to the bytestream of the new TCP connection (and similarly in the opposite direction).

Figure 1 summarizes how the new TCP connection is mapped to the QUIC stream. Actions and events of a TCP connection are translated to actions and events of the associated QUIC stream, so that a state transition on one is translated to the other.

+ +	ТСР	+	QUIC SI	ream		-+ -+
 +	SYN received FIN received RST received Data received	Open Send Send Send Send	Stream, Stream STOP_SE RESET_S Stream	send FIN ENDING STREAM data	TLVs	 -+
QUIC Stream			T(с СР	-+- -+	
 +	Stream opened, TLVs received Stream FIN received STOP_SENDING received RESET_STREAM received Stream data received			Send Send Send Send Send	SYN FIN RST RST data	-+

Figure 1: TCP connection to QUIC stream mapping

When sending STOP_SENDING or RESET_STREAM frames in response to the receipt of a TCP RST, QUIC tunnel peers MUST use the application protocol error code 0x00 (TCP_CONNECTION_RESET).

The QUIC stream-level flow control can be tuned to match the receive window size of the corresponding TCP connection, so that no excessive data needs to be buffered.

<u>4</u>. Connection establishment

The connection establishment follows the requirements described in Section 5 of [<u>I-D.piraux-quic-tunnel</u>].

In addition, the support of the stream mode is negotiated during the connection establishment by including the quic_tunnel_stream_mode transport parameter (value TBD). The parameter value has no meaning and SHOULD be null.

During the connection establishment, the concentrator can control the number of TCP bytestreams that can be opened initially by setting the initial_max_streams_bidi QUIC transport parameter as defined in [<u>I-D.ietf-quic-transport</u>].

Piraux & BonaventureExpires January 14, 2021[Page 4]

5. Messages format

In the following sections, we specify the format of each message introduced in this document. They are encoded using the TLV format described in [I-D.piraux-quic-tunnel].

5.1. QUIC tunnel stream TLVs

When using the stream mode, one or more messages are used to trigger and confirm the establishment of a connection towards the final destination for a given stream. Those messages are exchanged on this QUIC stream before the TCP connection bytestream. This section describes the format of these messages.

This document specifies the following QUIC tunnel stream TLVs:

Figure 2: QUIC tunnel stream TLVs

The TCP Connect TLV is used to request the establishment a TCP connection by the concentrator towards the final destination. The TCP Connect OK TLV confirms the establishment of this TCP connection. The Error TLV is used to indicate any error that occurred during the establishment of a TCP connection. Finally, the End TLV marks the end of the series of TLVs and the start of the bytestream on a given QUIC stream. These TLVs are detailed in the following sections.

Future versions of this document may define new TLVs. The End TLV allows a QUIC tunnel peer to send several TLVs before the start of the bytestream.

Of	fset 0	Offs	et 20	Offset 2	22
Client	V		V	V	
	+		+	+	
Stream 0	TCP Cor	nnect TLV	End TI	_V TCP	bytestream
	+		· ·	+	

Figure 3: Example of use of QUIC tunnel stream TLVs

Piraux & BonaventureExpires January 14, 2021[Page 5]

Figure 3 illustrates an example of use of QUIC tunnel streams TLVs. In this example, the client opens Stream 0 and sends two TLVs. The first one requests the concentrator to establish a new TCP connection. The second TLV marks the end of the series of TLV and the start of the TCP bytestream.

5.1.1. TCP Connect TLV

The TCP Connect TLV indicates the final destination of the TCP connection associated to a given QUIC stream. The fields Remote Peer Port and Remote Peer IP Address contain the destination port number and IP address of the final destination.

The Remote Peer IP Address MUST be encoded as an IPv6 address. IPv4 addresses MUST be encoded using the IPv4-Mapped IPv6 Address format defined in [<u>RFC4291</u>]. Further, the Remote Peer IP address field MUST NOT include multicast, broadcast, and host loopback addresses [<u>RFC6890</u>].

A QUIC tunnel peer MUST NOT send more than one TCP Connect TLV per QUIC stream. A QUIC tunnel peer MUST NOT send a TCP Connect TLV on non-self initiated streams.

Figure 4: TCP Connect TLV

5.1.2. TCP Connect OK TLV

The TCP Connect OK TLV does not contain a value. Its presence confirms the successful establishment of the requested TCP connection to the final destination. A QUIC peer MUST NOT send a TCP Connect OK TLV on self-initiated streams.

5.1.3. Error TLV

The Error TLV indicates out-of-band errors that occurred during the establishment of the TCP connection to the final destination. These errors can be ICMP Destination Unreachable messages for instance. In

Piraux & Bonaventure Expires January 14, 2021 [Page 6]

Internet-Draft

this case the ICMP packet received by the concentrator is copied inside the Error Payload field.

Figure 5: Error TLV

The following bytestream-level error codes are defined in this document:

+----+
| Code | Name |
+---++
0x0	Protocol Violation
0x1	ICMP Packet Received
0x2	Malformed TLV
0x3	Network Failure
+--++

Figure 6: Bytestream-level Error Codes

- Protocol Violation (0x0): A general error code for all nonconforming behaviors encountered. A QUIC tunnel peer SHOULD use a more specific error code when possible.
- o ICMP Packet Received (0x1): This code indicates that the concentrator received an ICMP packet while trying to create the associated TCP connection. The Error Payload contains the packet.
- Malformed TLV (0x2): This code indicates that a received TLV was not successfully parsed or formed. A peer receiving a TCP Connect TLV with an invalid IP address MUST send an Error TLV with this error code.
- o Network Failure (0x3): This codes indicates that a network failure prevented the establishment of the connection.

After sending one or more Error TLVs, the sender MUST send an End TLV and terminate the stream, i.e. set the FIN bit after the End TLV.

Piraux & BonaventureExpires January 14, 2021[Page 7]

5.1.4. End TLV

The End TLV does not contain a value. Its existence signals the end of the series of TLVs. The next byte in the QUIC stream after this TLV is part of of the tunneled bytestream.

6. Example flows

This section illustrates the different messages described previously and how they are used in a QUIC tunnel connection. For QUIC STREAM frames, we use the following syntax: STREAM[ID, Stream Data [, FIN]]. The first element is the Stream ID, the second is the Stream Data contained in the frame and the last one is optional and indicates that the FIN bit is set.

Client	Concentrato	or Final	Destination
STREAM[0, "TCP Connect,	End"]		
	>	SYN	
	====		======>
	[]	SYN+ACK	
SIREAMLO, TCP Connect OK	, End"] <===		
SIREAM[0, "bytestream d	ata"]		
	>	bytestream data,	ACK
	====		=====>
		bytestream data,	ACK
SIREAM[0, "bytestream	data"] <===		-====
<		FIN	
SIREAM[0, "", FIN]	<===		=======
<		ACK	
SIREAM[0, "", FIN]	====		-====>
	>	FIN	
	====		======>
		ACK	
	<===		-====

Legend:

--- QUIC connection === TCP connection

Figure 7: Example flow for the stream mode

On Figure 7, the client is initiating a TCP connection in stream mode to the Final Destination. A request and a response are exchanged, then the connection is torn down gracefully. A remote-initiated connection accepted by the concentrator on behalf of the client would have the order and the direction of all messages reversed.

Piraux & Bonaventure Expires January 14, 2021 [Page 8]

7. Security Considerations

<u>7.1</u>. Denial of Service

There is a risk of an amplification attack when the Concentrator sends a TCP SYN in response of a TCP Connect TLV. When a TCP SYN is larger than the client request, the Concentrator amplifies the client traffic. To mitigate such attacks, the Concentrator SHOULD rate limit the number of pending TCP Connect from a given client.

8. IANA Considerations

8.1. Registration of QUIC tunnel Identification String

This document creates a new registration for the identification of the QUIC tunnel protocol in the "Application Layer Protocol Negotiation (ALPN) Protocol IDs" registry established in [<u>RFC7301</u>].

The "qt" string identifies the QUIC tunnel protocol.

Protocol: QUIC tunnel

Identification Sequence: 0x71 0x74 ("qt")

Specification: This document

8.2. QUIC tunnel stream TLVs

IANA is requested to create a new "QUIC tunnel stream Parameters" registry.

The following subsections detail new registries within "QUIC tunnel stream Parameters" registry.

8.2.1. QUIC tunnel stream TLVs Types

IANA is request to create the "QUIC tunnel stream TLVs Types" subregistry. New values are assigned via IETF Review (<u>Section 4.8 of</u> [RFC8126]).

The initial values to be assigned at the creation of the registry are as follows:

++	+
Code Name ++	Reference
0 TCP Connect TLV 1 TCP Connect OK TLV 2 Error TLV 255 End TLV	[This-Doc] [This-Doc] [This-Doc] [This-Doc]
++	+

8.2.2. QUIC tunnel streams TLVs Error Types

IANA is request to create the "QUIC tunnel stream TLVs Error Types" sub-registry. New values are assigned via IETF Review (<u>Section 4.8</u> of [RFC8126]).

The initial values to be assigned at the creation of the registry are as follows:

8.3. QUIC Transport Parameter Registry

This document defines a new transport parameter for the negotiation of the stream mode. The following entry in Table 1 should be added to the "QUIC Transport Parameters" registry under the "QUIC Protocol" heading.

+----+
| Value | Parameter Name | Specification |
+----+
| TBD | quic_tunnel_stream_mode | Section 4 |
+---++

Table 1: Addition to QUIC Transport Parameters Entries
