ALTO Cost Calendar
draft-randriamasy-alto-cost-calendar-00

Abstract

The goal of Application-Layer Traffic Optimization (ALTO) is to bridge the gap between network and applications by provisioning network related information in order to allow applications to make informed decisions. The present draft proposes to extend the cost information provided by the ALTO protocol. The purpose is to broaden the decision possibilities of applications to not only decide 'where' to connect to, but also 'when'. This is useful to applications that have a degree of freedom on when to schedule data transfers, such as non- instantaneous data replication between data centers or service provisioning to end systems with irregular connectivity. ALTO guidance to schedule application traffic can also efficiently help for load balancing and resources efficiency.

The draft specifies a new Cost Mode, "Calendar" Mode, that is applicable to time-sensitive ALTO metrics and allows Applications to carefully schedule their connections or data transfers. In the Calendar Mode, an ALTO Server exposes ALTO Cost Values in JSON arrays where each value corresponds to a given time interval. The time intervals as well as other Calendar attributes are specified in the IRD. Besides the functional time-shift enhancement the ALTO Cost Calendar also allows to schedule the ALTO requests themselves and thus save a number of ALTO transactions.

Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC 2119](#) [[RFC2119](#)].

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on January 5, 2015.

[1.](#) Introduction

IETF is currently standardizing the ALTO protocol which aims for providing guidance to overlay applications, that need to select one or several hosts from a set of candidates that are able to provide a desired resource. This guidance is based on parameters that affect performance and efficiency of the data transmission between the hosts, e.g., the topological distance. The goal of ALTO is to improve the Quality of Experience (QoE) in the application while simultaneously optimizing resource usage in the underlying network infrastructure.

The ALTO protocol therefore [[ID-alto-protocol](#)] specifies a Network Map, which defines groupings of endpoints in a network region (called a PID) as seen by the ALTO server. The Endpoint Cost Service and the Endpoint (EP) Ranking Service then provide rankings for connections between the specified network regions and thus incentives for application clients to connect to ISP preferred endpoints, e.g. to reduce costs imposed to the network provider. Thereby ALTO intentionally avoids the provisioning of realtime information as explained in the ALTO Problem Statement [[RFC5693](#)] and ALTO Requirements [[RFC5693](#)]) drafts that write "Such information is better suited to be transferred through an in-band technique at the transport layer instead". Thus the current Cost Map and Endpoint Cost Service are providing, for a given Cost Type, exactly one rating per link between two PIDs or to an Endpoint. Applications are expected to query one of these two services in order to retrieve the currently valid cost values. They therefore need to plan their ALTO information requests according to the estimated frequency of cost value change. In case these value changes are predicable over a certain period of time and the application does not require immediate data transfer, it would save time to get the whole set of cost values over the period in one ALTO response and using these values to schedule data transfers would allow to optimise the network resources usage and QoE.

In this draft we introduce use cases that describe applications that have a degree of freedom on scheduling data transfers over a period of time, thus they do not need to start a transfer instantaneously on a retrieved request. For this kind of applications we propose to extend the Cost Map and Endpoint Cost Services by adding a calendar on the cost values, allowing applications to time-shift data transfers.

In addition to this functional ALTO enhancement, we expect to further gain by gathering multiple Cost Values for one cost type as firstly one Cost Map reporting on N Cost Values is less bulky than N Cost Maps containing one Cost value each and secondly, this reduces N ALTO transactions to a single one. This is valuable for both the storage of these ALTO maps and their transfer. Similar gains can be obtained for the ALTO Endpoint Cost Service.

In this draft an "ALTO Calendar" is presented as a Cost Mode that is applicable to time-sensitive ALTO metrics and allows applications using such metrics to carefully schedule their connections or data transfers. In the Calendar Mode, an ALTO Server exposes ALTO Cost Values in JSON arrays where each value corresponds to a given time interval. The time intervals as well as other Calendar attributes (the ones suggested by Richard) are specified in the IRD and allow the ALTO Client to interpret the received ALTO values. This draft proposes a set of Calendar attributes to be added to the IRD, for discussion in the ALTO WG.

The remainder of this draft first provides a variety of use cases that motivate the need for a 'calendar' cost mode. It then specifies the needed extensions to the ALTO protocol and details some example messages.

2. Motivating use cases for ALTO Cost Schedule

This section introduces use cases showing the benefits of providing ALTO Cost values in 'calendar' mode. Most likely, the ALTO Cost Calendar would be used for the Endpoint Cost Service, assuming that a limited set of feasible Endpoints for a non-real time application is already identified, that they do not need to be accessed immediately and that their access can be scheduled within a given time period. The Cost Map service, filtered or not, is also applicable as long as the size of the Map is manageable.

2.1. Bulk Data Transfer scheduling

Some CDNs are prepopulating caches with content before it actually gets available for the user and thus there is a degree of freedom on when the content is transmitted from the origin server to the caching

node. Other applications like Facebook or YouTube rely on data replication across multiple sites for several reasons, such as offloading the core network or increasing user experience through short latency. Typically the usage pattern of these data centers or caches follows a location dependent diurnal pattern.

In the examples above, data needs to be replicated across the various locations of a CDN provider, leading to bulk data transfers between datacenters. Scheduling these data transfers is a non-trivial task as the transfer should not infer with the user peak demand to avoid degradation of user experience and to decrease billing costs for the datacenter operator by leveraging off-peak hours for the transfer. This peak demand typically follows a diurnal pattern according to the geographic region of the datacenter. One precondition to schedule transfers however is to have a good knowledge about the demand and link utilization patterns between the different datacenters and networks.

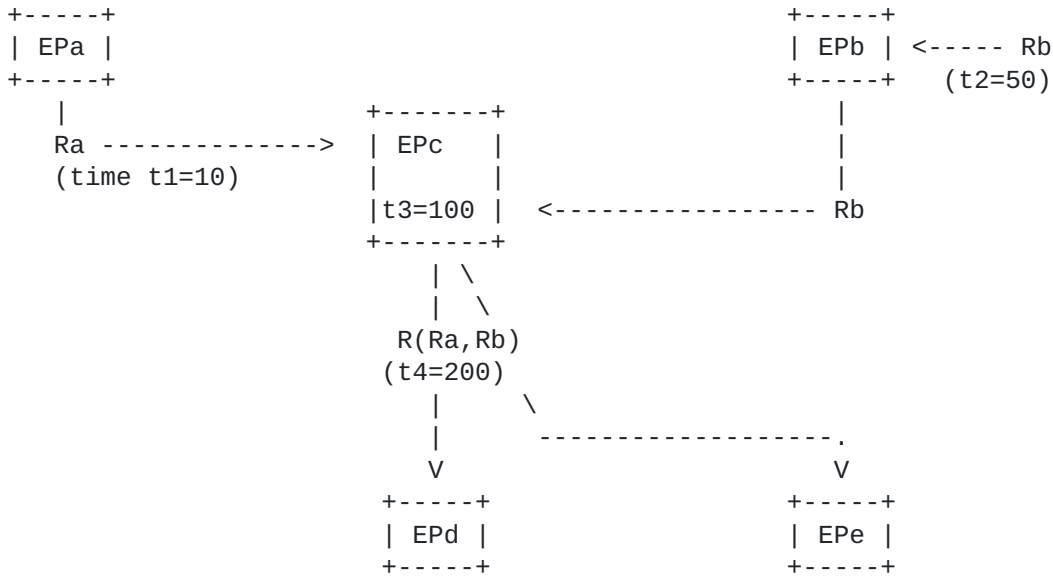

While this usage data today already is gathered and also used for the scheduling of data transfer, provisioning this data gets increasingly complex with the number of CDN nodes and in particular the number of datacenter operators that are involved. For example, privacy concerns prevent that this kind of data is shared across administrative domains. The ALTO Cost Calendar specified later in this document avoids this problem by presenting an abstracted view of time sensitive utilization maps through a dedicated ALTO service to allow CDN operators a mutual scheduling of such data transfers across administrative domains.

2.2. Endsystems with limited connectivity or access to datacenters

Another use case that benefits from the availability of multi-timeframe cost information is based on applications that are limited by their connectivity either in time or resources or both. For example applications running on devices in remote locations or in developing countries that need to synchronize their state with a data center periodically, in particular if sometimes there is no connection at all. Example applications is enterprise database update, remote learning, remote computation distributed on several data center endpoints.

Wireless connectivity has a variable quality or may even be intermittent. On the other hand, the connectivity conditions are often predicable. For non real time applications, it is thus desirable to provide ALTO clients with routing costs to connection nodes (i.e. Application Endpoints) over different time periods. This would allow end systems using ALTO aware application clients to schedule their connections to application endpoints.

Another challenge arises with end systems using resources located in datacenters and trading content and resources scattered around the world. For non-real time applications, the interaction with Endpoints can be scheduled at the time slots corresponding to the best possible QoE. For instance, resource Ra downloaded from Endpoint EPa at time t1, Resource Rb uploaded to EPb at time t2, some batch computation involving Ra and Rb done on EPc at time t3 and results R(A,B) downloaded to EPd and EPe at time t4. Example applications are similar to the ones cited in the previous paragraph.

Last, the ALTO Cost calendar is beneficial to optimizing ALTO transactions themselves. Indeed, let us assume that an Application Client is located in an end system with limited resources and/or has an access to the network that is either intermittent or provides an acceptable QoE in limited but predictable time periods. In that case, it needs to both schedule its resources demanding networking activities and its ALTO requests. Instead of having to figure out when the cost values may change and having to carefully schedule multiple ALTO requests, it could avoid this by relying on Cost Schedule attributes that indicate the time granularity, the validity and time scope of the cost information, together with the time related cost values themselves.

2.3. SDN Controller guided access to application endpoints

The Software Defined Networking (SDN), see [[sdnrg](#)], is a model that attempts to manage and reconfigure networks in a more flexible way in order to better cope with the traffic challenges posed by nowadays resources greedy applications. To this end, one option is "moving the control plane out of the network elements into "controllers", see [SDN charter, <http://www.1-4-5.net/~dmm/sdnrg/sdnrg.html>], that implements the network control and management. The SDN Controllers are deemed to gather the network state information and provide it in an abstracted form to SDN aware applications while gathering their requirements in QoE and exchanging other application "management" information and commands.

The relevance of ALTO to perform a number of SDN functions has been recently highlighted. An ALTO Server can assist an SDN Controller by hosting abstracted network information that can be provided to SDN aware applications via an ALTO Client. It can also assist other SDN Control operations using information in and outside the ALTO scope.

The SDN primitive "Get network resources" provides applications with informations allowing them to evaluate the expected QoE. QoE related information includes delay and bandwidth at the application endpoints as well as on the network paths. Such information may be provided via the ALTO Service by proposed extensions of the ALTO protocol that define new ALTO Cost Types allowing to abstract and report QoE to applications.

One key objective of an SDN controller is the ability to balance the application traffic whenever possible. For non real time applications, data and resources transfer can be time shifted, resources availability may often be predicible and last, strong incentives for applications to time shift their traffic may be given by network operators appropriately setting routing cost values at different time values, according to their policy to cope with network occupation over time.

To achieve this objective, the SDN controller can:

1. get the network state history from its controlled network elements through its southbound API
2. possibly derive an estimation or a prediction of these values over given time frames
3. compute estimates and/or network provider preferences on end to end paths and store their abstraction in an ALTO Server in the

form of ALTO Cost Calendar values defined for different time periods

4. deliver these values to the SDN applications via the ALTO Endpoint Cost Service, as estimations covering the past and/or the future and/or preferences.

This way:

- o On one hand, the applications get the best possible QoE, as they can pick the best time for them to access one or more Endpoints,
- o On the other hand the SDN controller achieves load balancing as it may guide the application traffic so as to better distribute the traffic over time, and thus optimize its resources usage.

Note that we distinguish between "estimates" that we see as value aggregations represented with units such as bytes, seconds, percentage and "preferences" that we see as abstracted costs or scores w.r.t. a metric or state such as 'routingcost', 'bandwidthscore', 'link quality'.

2.4. Large flow scheduling on extended ALTO topologies

[[draft-yang-alto-topology-00](#)] presents initial thinking on extending ALTO for topology exposure services, that would provide flexible abstractions based on the raw network topology. Among other features, an ALTO topology may expose several paths between a source (src) and destination (dst), or topology details may be provided on restricted parts. This work was presented to the ALTO WG at IETF88.

The presentation slides [[slides-88-alto-5-topology](#)] on [[draft-yang-alto-topology-00](#)] expose a use case entitled "Large Flow Scheduling". This case includes a "daylife example" where a Google Map service proposes multiple routes between 2 points A and B, each calculated w.r.t. length and estimated time. For each of these selected paths, the map service exposes a time-sensitive qualitative value taking 4 values between Slow and Fast. A user of this application may thus organize its transfer w.r.t. metrics, paths and time, provided s/he does not have to commute immediately.

The use case on Large flow scheduling on extended ALTO topologies in the present section illustrates one modality of ALTO topology service, that would expose several paths between end to end (src, dst) pairs, computed w.r.t. one of more metrics, possibly under given constraints. On top of this enriched topology service, non real-time applications may also choose the time of data/resources transfer, taking thus advantage of a richer set of decision variables.

The use case "Large Flow Scheduling" of presentation [[slides-88-alto-5-topology](#)] can thus be adapted as follows:

- o Step1 - obtain the set T transfer tasks {(src, dest, data)}
- o Step2 - identify one or more paths for each (src, dst): several information sources exist among which:
 - * (a) ALTO CostMap with a "path" metric, // not specified here
 - * (b) an ALTO Topology Service providing a path computation hint (e.g. w.r.t. routingcost and/or other metrics)
- o Step 3 - while T not empty:
 - * 1 - query for example values for some metric 'available bandwidth' on paths:
 - + to this end, query the values in the ALTO 'calendar' Mode: on the selected (src, dst) for a set of time intervals. With this mode, the ALTO client will receive an array of values, each applicable to a time slot .
 - * 2 - schedule data transfer at the time slots corresponding to the preferred value.

2.5. Time-sensitive TE metrics Calendaring

Draft [[draft-wu-alto-te-metrics](#)] , proposes to extend the set of ALTO metrics with 11 ALTO traffic engineering (TE) metrics to reflect measurement on network delay, jitter, packet loss, hop count, and bandwidth. ALTO TE metrics that are time-sensitive, either by nature such as bandwidth and delay related metrics, or due to "normally" changing network conditions or both.

The values of ALTO TE metrics are typically collected from routing protocols and provided in a non-real time manner. In "normally" changing network conditions, TE metric values remain uniformly distributed over given time intervals and can be aggregated over bigger time intervals of periodic patterns. For example, an ALTO Server may collect values for e.g. delay from a routing protocol produced by measurements done every second over a measurement period of 30 seconds. The ALTO Server may then aggregate these values over two measurement periods (i.e. 60 seconds) and repeat the operation as it wishes. Then every hour, the ALTO Server provides these delay values in 'calendar' mode, encoded as an array of 60 values, assumed to estimate network performance statistics on each minute of this hour.

Another example is Bandwidth Calendaring. Bandwidth Calendaring allows network operators to reserve resources in advance according to agreements with their customers, enabling them to transmit data with specified starting time and duration, for example, for a scheduled bulk data replication between data centers. Traditionally, this can be supported by a Network Management System operation such as path pre-establishment and activation on the agreed starting time. However, this does not provide efficient network usage since the established paths exclude the possibility of being used by other services even when they are not used for undertaking any service.

A Cost calendar provided by an ALTO server can support the scheduled bulk data replication application with better efficiency since it can alleviate the burden of processing on network elements. This requires the ALTO server to maintain the calendared TE cost metrics on the end to end paths associated to data transfer.

To support cost calendaring for these time-sensitive ALTO TE metrics, the network topology and the dynamicity of the traffic need to be considered. For example, a small topology with low density and low capacity that carries unpredictable, heavy and bursty traffic has few chances to exhibit stationary TE metric value patterns over large periods and would benefit to use the ALTO Calendar over smaller time slots. Some ALTO TE metric values, even aggregated over time may need to be updated at a frequency that would require doing ALTO request at a pace that would be overload both the ALTO Client and the Server.

3. Design considerations for an ALTO calendar

This section enumerates a set of challenges in designing the calendaring specifications, and will be updates upon discussions in the ALTO WG.

An ALTO Cost calendar provided by the ALTO Server is an array of values for a given metric, where each value corresponds to a time interval which length is specified for this metric in the IRD, together with other attributes describing the time scope of the calendar. Most likely, the ALTO Cost Calendar would be used for the Endpoint Cost Service, assuming that a limited set of feasible Endpoints for a non-real time application is already identified, that they do not need to be accessed immediately and that their access can be scheduled within a given time period. The Cost Map service, filtered or not, is also applicable as long as the size of the Map is manageable.

A calendar is used to schedule transfers of application data or services and has several characteristics:

- o the Calendar values are assumed to be stationary on each time interval,
- o the ALTO Server may provide values on past time periods that can be interpreted as historical experience and used to anticipate future cost values,
- o the ALTO Server may provide stationary values on present or future time periods that can be interpreted as predictions on cost values,
- o the ALTO Server may provide stationary values on time intervals covering the past, and/or present and/or future.
- o for metrics provided with units and claiming to be aggregated from network measurements, the values can be interpreted as estimations.
- o For abstracted metrics provided with no units such as the 'routingcost' defined in the base ALTO protocol or abstracted unitless scores on network performances such as some potential 'bandwidth score' or 'unreliability cost', the values can be interpreted as network provider preferences.

Design requirements for an ALTO calendar

- o needs to convey dateless cyclic network provider preferences expressed w.r.t. given ALTO metric values (e.g., hourly, daily, weekly measurement/prediction)
- o needs to convey dateless cyclic network status if the ALTO Server claims to provide aggregated information on network status (e.g., hourly, daily, weekly measurement/prediction)
- o needs to be able to convey the result of a particular instance of time (e.g., to convey predicted network status during a maintenance outage on July 4, 2014 from 5-7pm)
- o needs at least the following attributes to report on cyclic patterns:
 - * generic time zone,
 - * measurement estimation or preference value validity interval: combining <nb-int-unit> and <interval-unit> to reflect for example: 1hour, 2minutes, 1week, 1m onth

- * date range of the Calendar, e.g. number of intervals allowing to derive the calendar time range in terms of: year, month, week, day, hour, min, secs
- o needs to expose validity period of the calendar: indicating when the next ALTO Calendar for this date range should be fetched if needed,
- o needs to provide time stamps: last-update-time:
 - * last-update-time: the time that the metric values are computed ,
 - * next-update-time: when the client may fetch an update , that is calendars

4. ALTO extensions for a Cost Calendar

The usage of a time-related ALTO Cost Calendar is rather proactive in that it can be used like a "time table" to figure out the best time to schedule data transfer and also anticipate predictable events including predictable flash crowds. An ALTO Cost Calendar should be viewed as a synthetic abstraction of real measurements that can be historic or be a prediction for upcoming time periods.

Specifications on the cost "calendar" attributes are proposed here and will be completed in further versions of this draft, upon discussion with the ALTO WG.

4.1. ALTO Cost-Mode: Calendar

This draft introduces a new ALTO Cost Mode called "calendar". This mode applies preferably to Costs that can be expressed in a single-valued Cost Mode. In that sense, when the "numerical" mode is available for a Cost-Type, the cost expressed in the "calendar" mode is an extension of its expression from one value in the "numerical" mode to an array of several values varying over time.

Types of Cost values such as JSONBool can also be expressed in the "calendar" mode, as states may be "true" or "false" depending on given time periods. They may be expressed as a single value which is either "true" or "false" following a decision rule outside the ALTO protocol.

4.2. ALTO Calendar attributes in the IRD

To ensure that the application client understands the provided information in the cost calendar in an unambiguous way, we specify the Calendar attributes in the ALTO IRD "meta" information, that defines the time scope of the "calendared" cost values. The reference time zone for the provided values is UTC.

- o interval-unit:
 - * expresses the unit in which the duration of an ALTO calendar time interval duration is expressed. The time unit, ranges from "second" to "year".
- o nb-int-units:
 - * the number of time units per interval. For example: interval-unit=minute and nb-int-units=5 means that each calendar value is provided on a time interval that lasts 5 minutes.
- o calendar-start-date:
 - * the date corresponding to the first value in the array, expressed with a 2 to 4 digits sequence 'mn/hh/dd/mo/yyyy' to be interpreted as minute/hour/day/month/year
- o next-start-date:
 - * 'mn/hh/dd/mo/yyyy', to limit the number of provided values, in case for instance of frequently changing values, and schedule the next ALTO Calendar query, the starting date of the next calendar,
- o nb-intervals:
 - * the integer number of values of the cost calendar array, at least equal to 1.
- o calendar-time-zone:
 - * set to "UTC+hhmm", with hhmm quantifying the UTC time shift where hh designates the hour and mn the minutes.
- o
 - * next-calendar-update: the next date 'mn/hh/dd/mo/yyyy' at which the ALTO Calendar values will be updated in the ALTO Server,

o last-calendar-update:

- * the last date 'mn/hh/dd/mo/yyyy' at which ALTO Calendar values were updated in the ALTO Server.

Some remarks:

- another option to express the date format is to use HTTP header fields formats such as:

Date: Tue, 15 Nov 1994 08:12:31 GMT

- If the 'calendar-start-date' date is past, the application can also use the information to compute statistics on values provided by ALTO over time to guide applications. Besides some customized prediction the ALTO Client may guess their reliability w.r.t. some measured QoE.

- The attributes 'last-calendar-update' and 'next-calendar-update' reflect the update frequency and age of the ALTO Calendar information. The difference between these two dates is not necessarily constant. The ALTO Client should just consider that the ALTO Server does not find it necessary to update the Calendar values between these two dates. The ALTO Client may thus assume that the ALTO Server considers the values as valid or stationary during this period.

- Attribute 'next-start-date' is different and reflects the duration of the provided calendar. For example an ALTO Server may provide a calendar for ALTO values changing every 5 minutes. Each calendar is "1 hour" long and thus has 12 values. The ALTO Server may decide to update the 24 hourly calendars day. Note also that this example 5 minutes interval may be the aggregation of real TE measurements done every 30 seconds, but this latter aspect is outside the scope of this draft as it is to be specified in the definition of the ALTO metric.

4.3. Example of calendared information resources in the IRD

This section describes an example IRD and related ALTO calendar transaction in a scenario where an ALTO Server offers the Calendar mode for several Cost Types that are either specified in the base ALTO protocol, proposed in other drafts see [\[draft-wu-alto-te-metrics\]](#) or suggested here as examples, like a cost metric reporting on measured packet loss and called 'TEpktloss. The provided example transactions are based on the use cases of [section 2](#).

These examples describe situations where a client has the choice of trading content or resources with several Endpoints and needs to decide with which Endpoint it will trade and at what time. For instance, one may assume that the Endpoints are spread over different time-zones, or have intermittent access. The ALTO Calendar mode specified below allows these clients to retrieve Endpoint cost maps valid for a certain timeframe (e.g. 24 hours), and get a set of values, each applicable on a (e.g. hourly) slot. Thus the application can optimize the needed data transfer according to this information.

In the scenario of the present draft, the available Endpoint Costs metrics are: "routingcost", "AShopcount", 'TEpktloss' and 'Availbandwidth'. "routingcost" and "AShopcount" are available in the "numerical" Cost Mode and 'TEpktloss' , 'Availbandwidth' and "routingcost" as well are available in the "calendar" Cost Mode.

Last, we suppose that the ALTO Client GETs the IRD on Tuesday July 1st 2014 at 13:15 .

- o The Calendar for 'TEpktloss': consists of 12 values provided each on a time interval of 5 minutes, provided on a per hour basis, and updated every day at midnight UTC+4. The calendar is updated everyday at midnight.,
- o The Calendar for 'Availbandwidth': consists of 12 values. It is computed every day and updated at 0h00, for 24 hours, on time intervals lasting 2 hours, with the first interval starting at 0h00. This information is then used to enable applications to see which time intervals in a day are the most favorable to operate, and which "busy " time intervals should be avoided.
- o The Calendar for 'routingcost': consists of an array of 24 time intervals lasting each 1 hour. The routingcost calendar covers a 1 day period, starting at midnight. It is updated every week on sunday. An ALTO Client can thus store and use the needed routingcost calendars for maximum 1 week. This may be applicable for networks with poor or intermittent connectivity where the operator may integrate monetary as well as network performance metrics in the provided 'routingcost' values.

4.3.1. Example IRD with ALTO cost Calendars

The example IRD given in this section includes 2 particular URIs:

- o "http://alto.example.com/endpointcost/lookup", in which the ALTO Server offers the numerical mode for metrics "routingcost" and "AShopcount".

- o "http://alto.example.com/endpointcost/calendar/lookup", in which the ALTO Server provides "calendar" mode for metrics 'TEpktloss' and 'Availbandwidth' and 'routingcost'.

4.3.2. Example transaction for a routingcost Calendar to face intermittent connectivity

Let us assume an Application Client located in an end system with limited resources and having an access to the network that is either intermittent or provides an acceptable quality in limited but possibly predictable time periods. Therefore, it needs to both schedule its resources demanding networking activities and minimize its ALTO transactions.

The Application Client has the choice to trade content or resources with a set of Endpoints of moderate 'routingcost', and needs to decide with which Endpoint it will trade at what time. For instance, one may assume that the Endpoints are spread on different time-zones, or have intermittent access. In this example, the 'routingcost' is assumed constant for the scheduling period and the time sensitive decision metric is the path bandwidth reflected by a Cost type called 'pathoccupationcost'.

The ALTO Client embedded in the Application Client queries ALTO information on 'pathoccupationcost' for the 24 hours following (implicitly) the date of "lastupdate", as this resource is listed in the IRD.

```
POST endpointcost/calendar/lookup HTTP/1.1
```

```
Host: alto.example.com
```

```
Content-Length: [TODO]
```

```
Content-Type: application/alto-endpointcostparams+json
```

```
Accept: application/alto-endpointcost+json,application/alto-error+json
```

```
{
  "cost-type" : {"cost-mode" : "calendar", "cost-metric" : "routingcost"},
  "endpoints" : {
    "srcs": [ "ipv4:192.0.2.2" ],
    "dsts": [
      "ipv4:192.0.2.89",
      "ipv4:198.51.100.34",
      "ipv4:203.0.113.45"
    ]
  }
}
```

```
HTTP/1.1 200 OK
```

```
Content-Length: [TODO]
```

```
Content-Type: application/alto-endpointcost+json
```

```
{
  "meta" : {},
  "cost-type" : {"cost-mode" : "calendar", "cost-metric" : "routingcost"},
  "endpoint-cost-calendar-map" : {
    "ipv4:192.0.2.2": {
      "ipv4:192.0.2.89" : [7, ... 24 values],
      "ipv4:198.51.100.34" : [4, ... 24 values],
      "ipv4:203.0.113.45" : [2, ... 24 values]
    }
  }
}
```

4.3.3. Example transaction for a bandwidth calendar

One example of non-real time information that can be provisioned in a 'calendar' is the expected path bandwidth. While the transmission rate can be measured in real time by end systems, the operator of a data center is in the position of formulating preferences for given paths, at given time periods of given time scales, for example to avoid hotspots due to diurnal usage patterns. In this example, we assume that an ALTO Client requests a bandwidth calendar as specified in the IRD to shedule its bulk data transfers as described in the use cases of sections [2.1](#) and [2.5](#).

POST endpointcost/calendar/lookup HTTP/1.1

Host: alto.example.com

Content-Length: [TODO]

Content-Type: application/alto-endpointcostparams+json

Accept: application/alto-endpointcost+json,application/alto-error+json

```
{
  "cost-type" : {"cost-mode" : "calendar", "cost-metric" : "Availbandwidth"},
  "endpoints" : {
    "srcs": [ "ipv4:192.0.2.2" ],
    "dsts": [
      "ipv4:192.0.2.89",
      "ipv4:198.51.100.34",
      "ipv4:203.0.113.45"
    ]
  }
}
```

HTTP/1.1 200 OK

Content-Length: [TODO]

Content-Type: application/alto-endpointcost+json

```
{
  "meta" : {},
  "cost-type" : {"cost-mode" : "calendar", "cost-metric" : "Availbandwidth"},
  "endpoint-cost-calendar-map" : {
    "ipv4:192.0.2.2": {
      "ipv4:192.0.2.89" : [7, ... 12 values],
      "ipv4:198.51.100.34" : [4, ... 12 values],
      "ipv4:203.0.113.45" : [2, ... 12 values]
    }
  }
}
```

5. IANA Considerations

Information for the ALTO Endpoint property registry maintained by the IANA and related to the new Endpoints supported by the acting ALTO server. These definitions will be formulated according to the syntax defined in Section on "ALTO Endpoint Property Registry" of [\[ID-alto-protocol\]](#),

Information for the ALTO Cost Type Registry maintained by the IANA and related to the new Cost Types supported by the acting ALTO server. These definitions will be formulated according to the syntax

defined in Section on "ALTO Cost Type Registry" of [\[ID-alto-protocol\]](#),

5.1. Information for IANA on proposed Cost Types

When a new ALTO Cost Type is defined, accepted by the ALTO working group and requests for IANA registration MUST include the following information, detailed in [Section 11.2](#): Identifier, Intended Semantics, Security Considerations.

5.2. Information for IANA on proposed Endpoint Properties

Likewise, an ALTO Endpoint Property Registry could serve the same purposes as the ALTO Cost Type registry. Application to IANA registration for Endpoint Properties would follow a similar process.

6. Acknowledgements

Thank you to D. Lopez, H. Peng and the ALTO WG for fruitful discussions.
