**YANG Data Model for MPLS LDP and mLDP**  
**[draft-raza-mpls-ldp-mldp-yang-03](#)**

## Abstract

This document describes a YANG data model for Multi-Protocol Label Switching (MPLS) Label Distribution Protocol (LDP) and Multipoint LDP (mLDP).

## Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on September 22, 2016.

[Page 2]

## **1. Introduction**

The Network Configuration Protocol (NETCONF) [[RFC6241](#)] is one of the network management protocols that defines mechanisms to manage network devices. YANG [[RFC6020](#)] is a modular language that represents data structures in an XML tree format, and is used as a data modelling language for the NETCONF.

This document introduces a YANG data model for MPLS Label Distribution Protocol (LDP) [[RFC5036](#)] and Multipoint LDP (mLDP) [[RFC6388](#)]. For LDP, it also covers LDP IPv6 [[RFC7552](#)] and LDP capabilities [[RFC5561](#)].

The data model is defined for following constructs that are used for managing the protocol:

- o Configuration
- o Operational State
- o Executables (Actions)
- o Notifications

This document is organized to define the data model for each of the above constructs (configuration, state, action, and notifications) in the sequence as listed earlier. Given that mLDP is tightly coupled with LDP, mLDP data model is defined under LDP tree and in the sequence as listed above as well.

## **2. Specification of Requirements**

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [[RFC2119](#)].

In this document, the word "IP" is used to refer to both IPv4 and IPv6, unless otherwise explicitly stated. For example, "IP address family" means and be read as "IPv4 and/or IPv6 address family"

## **3. LDP YANG Model**

### **3.1. Overview**

This document defines a new module named "ietf-mpls-ldp" for LDP/mLDP data models such that this module augments "mpls" list in "ietf-mpls" module that is defined in [[I-D.saad-mpls-static-yang](#)].

Raza, et al.

Expires September 22, 2016

[Page 3]

There are four main containers in "ietf-mpls-ldp" module as follows:

- o Read-Write parameters for configuration (Discussed in [Section 3.2](#))
- o Read-only parameters for operational state (Discussed in [Section 3.3](#))
- o Notifications for events (Discussed in [Section 3.4](#))
- o RPCs for executing commands to perform some action (Discussed in [Section 3.5](#))

For the configuration and state data, this model follows the approach described in [[I-D.openconfig-netmod-opstate](#)] to represent the configuration (intended state) and operational (applied and derived) state. This means that for every configuration (rw) item, there is an associated (ro) item under "state" container to represent the applied state. Furthermore, protocol derived state is also kept under "state" tree corresponding to the protocol area (discovery, peer etc.).

Following diagram depicts high level LDP yang tree organization and hierarchy:

```
module: ietf-mpls-ldp
```

```
  +-+ rw routing
```

```
    +-+ rw routing-instance [name]
```

```
      +-+ rw mpls
```

```
        +-+ rw mpls-ldp
```

```
          +-+ rw global
```

```
            |  +-+ rw config
```

```
            |  +-+ rw ...
```

```
            |  +-+ ro state
```

```
            |  +-+ ro ...
```

```
            |  .
```

```
          +-+ rw ...
```

```
          |
```

```
          |
```

```
        +-+ rw ...
```

```
        .
```

```
rpcs:
```

```
  +-+ x mpls-ldp-xxx
```

```
  +-+ x . . . . .
```

```
notifications:
```

```
  +--- n mpls-ldp-yyy
```

```
  +--- n ...
```

Figure 1

Before going into data model details, it is important to take note of the following points:

- o This module aims to address only the core LDP/mLDP parameters as per RFC specification, as well as some widely used and deployed non-RFC features. Any vendor specific feature should be defined in a vendor-specific augmentation of this model.
- o Multi-topology LDP [[RFC7307](#)] and Multi-topology mLDP [[I-D.iwijnand-mpls-mldp-multi-topology](#)] are beyond the scope of this document.
- o This module does not cover any applications running on top of LDP and mLDP, nor does it cover any OAM procedures for LDP and mLDP.
- o This model is a VPN Forwarding and Routing (VRF)-centric model and hence falls under an MPLS routing-instance. It is important to note that [[RFC4364](#)] defines VRF tables and default forwarding tables as different, however from a yang modelling perspective

Raza, et al.

Expires September 22, 2016

[Page 5]

this introduces unnecessary complications, hence we are treating the default forwarding table as just another VRF.

- o A "routing-instance" refers to a VRF instance (both default and non-default) within the scope of this model.
- o This model supports two address-families, namely "ipv4" and "ipv6".
- o This model assumes platform-wide label space (i.e. label space Id of zero).
- o The label and peer policies (including filters) are defined using a prefix-list. When used for a peer policy, the prefix refers to the LSR Id of the peer. The prefix-list is referenced from routing-policy model as defined in [[I-D.ietf-rtgwg-policy-model](#)].
- o The use of grouping (templates) for bundling and grouping the configuration items is not employed in current revision, and is a subject for consideration in future.
- o This model uses the terms LDP neighbor/adjacency, session, and peer more strictly than [RFC 5036](#) does. In this model, these terms are meant as follows:
  - \* Neighbor/Adjacency: An LDP enabled LSR that is discovered by LDP discovery mechanisms.
  - \* Session: An LDP neighbor with whom a TCP connection has been established
  - \* Peer: An LDP session which has successfully progressed beyond its initialization phase and is ready for binding exchange.

When used in this document, the above terms will refer strictly to the semantics and definitions defined for them.

A graphical representation of LDP YANG data model is presented in Figure 3, Figure 5, Figure 11, and Figure 12. Whereas, the actual model definition in YANG is captured in [Section 5](#).

### [3.2. Configuration](#)

This specification defines the configuration parameters for base LDP as defined in [[RFC5036](#)] and LDP IPv6 [[RFC7552](#)]. Moreover, it incorporates provisions to enable LDP Capabilities [[RFC5561](#)], and defines some of the most significant and commonly used capabilities

Raza, et al.

Expires September 22, 2016

[Page 6]

such as Typed Wildcard FEC [[RFC5918](#)], End-of-LIB [[RFC5919](#)], and LDP Upstream Label Assignment [[RFC6389](#)].

This specification supports VRF-centric configuration. For implementations that support protocol-centric configuration, with provision for inheritance and items that apply to all vrf's, we recommend an augmentation of this model such that any protocol-centric or all-vrf configuration is defined under their designated containers within the standard routing-instance (please see section [Section 3.2.2](#))

This model augments MPLS configuration as defined in MPLS base specification [[I-D.saad-mpls-static-yang](#)]. For LDP interfaces, this model still uses its own container and leaf, and is subject to alignment in future once MPLS interface model is solidified in MPLS base specification. Furthermore, as mentioned earlier, the configuration tree presents read-write intended configuration leave/items as well as read-only state of the applied configuration. The former is listed under "config" container and latter under "state" container.

Following is high-level configuration organization for LDP/mLDP:

```
module: ietf-mpls-ldp
  +-+ routing
    +-+ routing-instance [name]
      +-+ mpls
        +-+ mpls-ldp
          +-+ global
            |   +-+ ...
            |   +-+ ...
            |   +-+ address-family* [afi]
            |     +-+ ...
            |     +-+ ...
            |   +-+ discovery
            |     +-+ ...
        +-+ peers
          +-+ ...
          +-+ ...
```

Figure 2

Given the configuration hierarchy, the model allows inheritance such that an item in a child tree is able to derive value from a similar or related item in one of the parent. For instance, hello holdtime can be configured per-VRF or per-VRF-interface, thus allowing

Raza, et al.

Expires September 22, 2016

[Page 7]

inheritance as well flexibility to override with a different value on any child level.

Following is a simplified graphical representation of the data model for LDP configuration

```

module: ietf-mpls-ldp
augment /rt:routing/rt:routing-instance/mpls:mpls:
  +-rw mpls-ldp!

Figure 3

### 3.2.1. Configuration Hierarchy

The LDP configuration container is logically divided into following high-level config areas:

```
Per-VRF parameters
  o Global parameters
  o Per-address-family parameters
  o LDP Capabilities parameters
  o Hello Discovery parameters
    - interfaces
      - Per-interface:
        Global
        Per-address-family
    - targeted
      - Per-target
  o Peer parameters
    - Global
    - Per-peer
      Per-address-family
      Capabilities parameters
  o Forwarding parameters
```

Figure 4

Following subsections briefly explain these configuration areas.

### **3.2.1.1. Per-VRF parameters**

LDP module resides under an MPLS routing-instance and the scope of any LDP configuration defined under this tree is per routing-instance (per-VRF). This configuration is further divided into sub categories as follows.

#### **3.2.1.1.1. Per-VRF global parameters**

There are configuration items that are available directly under a VRF instance and do not fall under any other sub tree. Example of such a parameter is LDP LSR id that is typically configured per VRF. To keep legacy LDP features and applications working in an LDP IPv4 networks with this model, this document recommends an operator to pick a routable IPv4 unicast address as an LSR Id.

#### **3.2.1.1.2. Per-VRF Capabilities parameters**

This container falls under global tree and holds the LDP capabilities that are to be enabled for certain features. By default, an LDP capability is disabled unless explicitly enabled. These capabilities are typically used to negotiate with LDP peer(s) the support/non-support related to a feature and its parameters. The scope of a capability enabled under this container applies to all LDP peers in the given VRF instance. There is also a per-peer level capability

Raza, et al.

Expires September 22, 2016

[Page 12]

container that is provided to override a capability that is enabled/specify at VRF level.

#### **3.2.1.1.3. Per-VRF Per-Address-Family parameters**

Any LDP configuration parameter related to IP address family (AF) whose scope is VRF wide is configured under this tree. The examples of per-AF parameters include enabling an address family, prefix-list based label policies, and LDP transport address.

#### **3.2.1.1.4. Per-VRF Hello Discovery parameters**

This container is used to hold LDP configuration related to Hello and discovery process for both basic (link) and extended (targeted) discovery.

The "interfaces" is a container to configure parameters related to VRF interfaces. There are parameters that apply to all interfaces (such as hello timers), as well as parameters that can be configured per-interface. Hence, an interface list is defined under "interfaces" container. The model defines parameters to configure per-interface non AF related items, as well as per-interface per-AF items. The example of former is interface hello timers, and example of latter is enabling hellos for a given AF under an interface. [Ed note: TODO: Align with IETF MPLS base interface model once IETF MPLS base model gets matured]

The "targeted" container under a VRF instance allows to configure LDP targeted discovery related parameters. Within this container, the "target" list provides a mean to configure multiple target addresses to perform extended discovery to a specific destination target, as well as to fine-tune the per-target parameters.

#### **3.2.1.1.5. Per-VRF Peer parameters**

This container is used to hold LDP configuration related to LDP sessions and peers under a VRF instance. This container allows to configure parameters that either apply on VRF's all peers or a subset (peer-list) of VRF peers. The example of such parameters include authentication password, session KA timers etc. Moreover, the model also allows per-peer parameter tuning by specifying a "peer" list under the "peers" container. A peer is uniquely identified using its LSR Id and hence LSR Id is the key for peer list

Like per-interface parameters, some per-peer parameters are AF-agnostic (i.e. either non AF related or apply to both IP address families), and some that belong to an AF. The example of former is per-peer session password configuration, whereas the example of

latter is prefix-list based label policies (inbound and outbound) that apply to a given peer.

### **3.2.1.1.6. Per-VRF Forwarding parameters**

This container is used to hold configuration used to control LDP forwarding behavior under a VRF instance. One example of a configuration under this container is when a user wishes to enable neighbor discovery on an interface but wishes to disable use of the same interface as forwarding nexthop. This example configuration makes sense only when there are more than one LDP enabled interfaces towards the neighbor.

### **3.2.2. All-VRFs Configuration**

[Ed note: TODO]

### **3.3. Operational State**

Operational state of LDP can be queried and obtained from this read-only container "mpls-ldp" which is augmented from "routing" of MPLS tree (/rt:routing/rt:routing-instance/mpls:mpls).

Please note this state tree refers both the configuration "applied" state as well as the "derived" state related to the protocol.

Following is a simplified graphical representation of the data model for LDP operational state.

```
module: ietf-mpls-ldp
augment /rt:routing/rt:routing-instance/mpls:mpls:

### Figure 5

#### **3.3.1. Derived States**

Following are main areas for which LDP operational derived state is defined:

Neighbor Adjacencies

Peer

Bindings (FEC-label and address)

Capabilities

##### **3.3.1.1. Adjacency state**

Neighbor adjacencies are per address-family hello adjacencies that are formed with neighbors as result of LDP basic or extended discovery. In terms of organization, there is a source of discovery (e.g. interface or target address) along with its associated parameters and one or more discovered neighbors along with neighbor discovery related parameters. For the basic discovery, there could be more than one discovered neighbor for a given source (interface), whereas there is at most one discovered neighbor for an extended discovery source (local-address and target-address). This is also to be noted that the reason for a targeted neighbor adjacency could be either an active source (locally configured targeted) or passive source (to allow any incoming extended/targeted hellos). A neighbor/adjacency record also contains session-state that helps highlight whether a given adjacency has progressed to subsequent session level or to eventual peer level.

Following captures high level tree hierarchy for neighbor adjacency state.

```
+--rw mpls-ldp!
  +-rw discovery
    +-rw interfaces
      | +-rw interface* [interface]
      |   +-rw address-family* [af]

address]
          +-ro local-address
          +-ro adjacent-address
          . . .
```

Figure 6

### 3.3.1.2. Peer state

Peer related derived state is presented under peers tree. This is one of the core state that provides info on the session related parameters (mode, authentication, KA timeout etc.), TCP connection info, hello adjacencies for the peer, statistics related to messages and bindings, and capabilities exchange info.

Following captures high level tree hierarchy for peer state.

### [3.3.1.3. Bindings state](#)

Binding state provides information on LDP FEC-label bindings as well as address binding for both inbound (received) as well as outbound (advertised). FEC-label bindings are presented as a FEC-centric view, and address bindings are presented as an address-centric view:

FEC-Label bindings:

FEC 200.1.1.1/32:

advertised: local-label 16000  
peer 192.168.0.2:0  
peer 192.168.0.3:0  
peer 192.168.0.4:0

received:

peer 192.168.0.2:0, label 16002, used-in-forwarding=Yes  
peer 192.168.0.3:0, label 17002, used-in-forwarding=No

FEC 200.1.1.2/32:

. . .

FEC 201.1.0.0/16:

. . .

Address bindings:

Addr 1.1.1.1:

advertised

Addr 1.1.1.2:

advertised

Addr 2.2.2.2:

[Page 25]

### [3.4. Notifications](#)

This model defines a list of notifications to inform client of important events detected during the protocol operation. These events include events related to changes in the operational state of an LDP peer, hello adjacency, and FEC etc. It is to be noted that an LDP FEC is treated as operational (up) as long as it has at least 1 NHLFE with outgoing label.

Following is a simplified graphical representation of the data model for LDP notifications.

```
module: ietf-mpls-ldp
notifications:
  +--n mpls-ldp-peer-event
    |  +-ro event-type?          oper-status-event-type
    |  +-ro routing-instance-ref? rt:routing-instance-ref
    |  +-ro peer-ref?           leafref
  +--n mpls-ldp-hello-adjacency-event
    |  +-ro event-type?          oper-status-event-type
    |  +-ro routing-instance-ref? rt:routing-instance-ref
    |  +-ro (hello-adjacency-type)?
      |    +--:(targeted)
      |      |  +-ro targeted
      |      |  +-ro target-address?  inet:ip-address
      |    +--:(link)
      |      +-ro link
      |        +-ro next-hop-interface?  if:interface-ref
      |        +-ro next-hop-address?   inet:ip-address
  +--n mpls-ldp-fec-event
    +-ro event-type?          oper-status-event-type
    +-ro routing-instance-ref? rt:routing-instance-ref
    +-ro prefix?              inet:ip-prefix
```

Figure 11

### [3.5. Actions](#)

This model defines a list of rpcs that allow performing an action or executing a command on the protocol. For example, it allows to clear (reset) LDP peers, hello-adjacencies, and statistics. The model makes an effort to provide different level of control so that a user is able to either clear all, or clear all of a given type, or clear a specific entity.

Raza, et al.

Expires September 22, 2016

[Page 26]

Following is a simplified graphical representation of the data model for LDP actions.

```
module: ietf-mpls-ldp
rpcs:
  +---x mpls-ldp-clear-peer
    |   +---w input
    |   |   +---w routing-instance-ref?  rt:routing-instance-ref
    |   |   +---w lsr-id?                union
  +---x mpls-ldp-clear-hello-adjacency
    |   +---w input
    |   |   +---w routing-instance-ref?  rt:routing-instance-ref
    |   |   +---w hello-adjacency
    |   |   |   +---w (hello-adjacency-type)?
    |   |   |   +---:(targeted)
    |   |   |   |   +---w targeted!

```

Figure 12

## [4. mLDP YANG Model](#)

### [4.1. Overview](#)

Due to tight dependency of mLDP on LDP, mLDP model builds on top of LDP model defined earlier in the document. Following are the main mLDP areas and documents that are within the scope of this model:

- o mLDP Base Specification [[RFC6388](#)]
- o mLDP Recursive FEC [[RFC6512](#)]
- o Targeted mLDP [[RFC7060](#)]
- o mLDP Fast-Reroute (FRR)
  - \* Node Protection [[RFC7715](#)]

- \* Multicast-only
- o Hub-and-Spoke Multipoint LSPs [[RFC7140](#)]
- o mLDP In-band Signaling [[RFC6826](#)] (future revision)
- o mLDP In-band Signaling with Wildcards [[RFC7438](#)] (future revision)
- o Configured Leaf LSPs (manually provisioned)

[Ed Note: Some of the topics in the above list are to be addressed/added in later revision of this document].

## **4.2. Configuration**

### **4.2.1. Configuration Hierarchy**

In terms of overall configuration layout, following figure highlights extensions to LDP configuration model to incorporate mLDP:

```
+-- mpls-ldp
  +- ...
  +- ...
  +- mldp
    |  +- ...
    |  +- ...
    |  +- address-family* [af]
      +- af
        +- ...
        +- ...
    +- global
      +- ...
      +- capability
        +- ...
        +- ...
      +- mldp
        +- ...
        +- ...
  +- discovery
    +- ...
    +- ...
  +- forwarding-nexthop
    +- interfaces
      +- interface* [interface]
        +- interface
        +- address-family* [af]
          +- af
          +- ...
        +- mldp-disable
  +- peers
    +- ...
    +- ...
    +- peer* [lsrc-id]
      +- ...
      +- ...
      +- capability
        +- ...
        +- ...
      +- mldp
        +- ...
        +- ...
```

Figure 13

From above hierarchy, we can categorize mLDP configuration parameters into two types:

Raza, et al.

Expires September 22, 2016

[Page 29]

- o Parameters that leverage/extend LDP containers and parameters
- o Parameters that are mLDP specific

Following subsections first describe mLDP specific configuration parameters, followed by those leveraging LDP.

#### **4.2.2. mldp container**

mldp container resides directly under "mpls-ldp" and holds the configuration related to items that are mLDP specific. The main items under this container are:

- o mLDP enabling: To enable mLDP under a (VRF) routing instance, mldp container is enabled under LDP. Given that mLDP requires LDP signalling, it is not sensible to allow disabling LDP control plane under a (VRF) routing-instance while requiring mLDP to be enabled for the same. However, if a user wishes only to allow signalling for multipoint FECs on an LDP/mLDP enabled VRF instance, he/she can use LDP label-policies to disable unicast FECs under the VRF.
- o mLDP per-AF features: mLDP manages its own list of IP address-families and the features enabled underneath. The per-AF mLDP configuration items include:
  - \* Multicast-only FRR: This enables Multicast-only FRR functionality for a given AF under mLDP. The feature allows route-policy to be configured for finer control/applicability of the feature.
  - \* Recursive FEC: The recursive-fec feature [[RFC6512](#)] can be enabled per AF with a route-policy.
  - \* Configured Leaf LSPs: To provision multipoint leaf LSP manually, a container is provided per-AF under LDP. The configuration is flexible and allows a user to specify MP LSPs of type p2mp or mp2mp with IPv4 or IPv6 root address(es) by using either LSP-Id or (S,G).

Targeted mLDP feature specification [[RFC7060](#)] do not require any mLDP specific configuration. It, however, requires LDP upstream-label-assignment capability to be enabled.

Raza, et al.

Expires September 22, 2016

[Page 30]

#### **4.2.3. Leveraging LDP containers**

mLDP configuration model leverages following configuration areas and containers that are already defined for LDP:

- o Capabilities: A new container "mldp" is defined under Capabilities container. This new container specifies any mLDP specific capabilities and their parameters. Moreover, a new "mldp" container is also added under per-peer capability container to override/control mLDP specific capabilities on a peer level. In the scope of this document, the most important capabilities related to mLDP are p2mp, mp2mp, make-before-break, hub-and-spoke, and node-protection.
- o Discovery and Peer: mLDP requires LDP discovery and peer procedures to form mLDP peering. A peer is treated as mLDP peer only when either P2MP or MP2MP capabilities have been successfully exchanged with the peer. If a user wish to selectively enable or disable mLDP with a mLDP-enabled peer, he/she may use per-peer mLDP capabilities configuration. [Ed Note: The option to control mLDP enabling/disabling on a peer-list is being explored for future ]. In most common deployments, it is desirable to disable mLDP (capabilities announcements) on a targeted-only LDP peering, where targeted-only peer is the one whose discovery sources are targeted only. In future revision, a configuration option for this support will also be provided.
- o Forwarding: By default, mLDP is allowed to select any of the LDP enabled interface as a downstream interface towards a nexthop (LDP/mLDP peer) for MP LSP programming. However, a configuration option is provided to allow mLDP to exclude a given interface from such a selection. Note that such a configuration option will be useful only when there are more than one interfaces available for the downstream selection.

This goes without saying that mLDP configuration tree follows the same approach as LDP, where the tree comprise leafs for intended configuration.

#### **4.2.4. YANG tree**

The following figure captures the YANG tree for mLDP configuration. To keep the focus, the figure has been simplified to display only mLDP items and not LDP items.

```
module: ietf-mpls-ldp
augment /rt:routing/rt:routing-instance/mpls:mpls:
```

```
+--rw mpls-ldp!
  +-rw global
  |  +-rw config
  |  |  +-rw capability
  |  |  |  +-rw mldp {mldp}?

#### [4.3. Operational State](#)

Operational state of mLDP can be queried and obtained from this read-only container "mldp" which resides under mpls-ldp container. Please note that "applied" state of an mLDP configuration item is already captured under mldp configuration tree. This mldp state tree only refers to the "derived" state related to mLDP protocol.

Following is a simplified graphical representation of the data model for mLDP operational state for applied state. [Ed note: Derived state for mldp is TODO]

```
module: ietf-mpls-ldp
augment /rt:routing/rt:routing-instance/mpls:mpls:
  +-rw mpls-ldp!
    +-rw global
      |  +-ro state
      |  |  +-ro capability
      |  |  |  +-ro mldp {mldp}?

#### 4.4. Notifications

mLDP notification module consists of notification related to changes in the operational state of an mLDP FEC. Following is a simplified graphical representation of the data model for mLDP notifications:

```
module: ietf-mpls-ldp
notifications:
  +--n mpls-mldp-fec-event
    +--ro event-type?          oper-status-event-type
    +--ro routing-instance-ref? rt:routing-instance-ref
    +--ro tree-type?          multipoint-type
    +--ro root?                inet:ip-address
    +--ro (lsp-key-type)?
      +--:(lsp-id-based)
        |  +--ro lsp-id?          uint16
      +--:(source-group-based)
        +--ro source-address?    inet:ip-address
        +--ro group-address?    inet:ip-address
```

Figure 16

#### 4.5. Actions

Currently, no RPCs/actions are defined for mLDP.

### 5. YANG Specification

Following are actual YANG definition for LDP and mLDP constructs defined earlier in the document.

```
<CODE BEGINS> file "ietf-mpls-ldp@2016-03-18.yang" -->

module ietf-mpls-ldp {
  namespace "urn:ietf:params:xml:ns:yang:ietf-mpls-ldp";
  // replace with IANA namespace when assigned
  prefix ldp;

## **6. Security Considerations**

The configuration, state, action and notification data defined using YANG data models in this document are likely to be accessed via the protocols such as NETCONF [[RFC6241](#)] etc.

Hence, YANG implementations MUST comply with the security requirements specified in [section 15 of \[RFC6020\]](#). Additionally, NETCONF implementations MUST comply with the security requirements specified in sections [2.2](#), [2.3](#) and [9](#) of [[RFC6241](#)] as well as [section 3.7 of \[RFC6536\]](#).

## **7. IANA Considerations**

This document does not extend LDP or mLDP base protocol specification and hence there are no IANA considerations.

Note to the RFC Editor: Please remove IANA section before the publication.

## **8. Acknowledgments**

The authors would like to acknowledge Eddie Chami, Nagendra Kumar, Mannan Venkatesan, Pavan Beeram for their contribution to this

Raza, et al.
