The Security Evaluated Standardized Password Authenticated Key Exchange  
(SESPAKE) Protocol  
[draft-smyshlyayev-sespaKE-06](#)

## Abstract

This document specifies the Security Evaluated Standardized Password Authenticated Key Exchange (SESPAKE) protocol. The SESPANE protocol provides password authenticated key exchange for usage in the systems for protection of sensitive information. The security proofs of the protocol was made for the case of an active adversary in the channel, including MitM attacks and attacks based on the impersonation of one of the subjects.

## Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on December 5, 2016.

## [1. Introduction](#)

The current document contains the description of the password authenticated key exchange protocol SESPAKE (security evaluated standardized password authenticated key exchange) for usage in the systems for protection of sensitive information. The protocol is intended to use for establishment of keys that are then used for organization of secure channel for protection of sensitive information. The security proofs of the protocol was made for the case of an active adversary in the channel, including MitM attacks and attacks based on the impersonation of one of the subjects.

## [2. Conventions used in this document](#)

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [[RFC2119](#)].

## [3. Notations](#)

This document uses the following parameters of elliptic curves in accordance with [[RFC6090](#)].

Smyshlyaev, et al.

Expires December 5, 2016

[Page 2]

E an elliptic curve defined over a finite prime field GF( $p$ ), where  $p > 3$ ;

p the characteristic of the underlying prime field;

a, b the coefficients of the equation of the elliptic curve in the canonical form;

m the elliptic curve group order;

q the elliptic curve subgroup order;

P generator of the subgroup of order q;

X, Y the coordinates of the elliptic curve point in the canonical form;

0 zero point (point of infinity) of the elliptic curve.

This memo uses the following functions:

HASH the underlying hash function;

HMAC the function for calculating a message authentication code, based on a HASH function in accordance with [\[RFC2104\]](#);

F(PW, salt, n) the value of the function PBKDF2(PW,salt,n,len), where PBKDF2(PW,salt,n,len) is calculated according to [\[RFC2898\]](#) The parameter len is considered equal to minimal integer that is a multiple of 8 and satisfies the following condition:  
 $\text{len} \geq \text{floor}(\log_2(q))$ .

This document uses the following terms and definitions for the sets and operations on the elements of these sets

$B_n$  the set of byte strings of size  $n$ ,  $n \geq 0$ , for  $n = 0$  the  $B_n$  set consists of a single empty string of size 0; if  $b$  is an element of  $B_n$ , then  $b = (b_1, \dots, b_n)$ , where  $b_1, \dots, b_n$  are elements of  $\{0, \dots, 255\}$ ;

$\text{int}(w')$  if the byte string  $w' = (w_1, \dots, w_t)$  is in  $B_t$ , then  $\text{int}(w')$  is an integer  $w = 256^{(t-1)}w_t + \dots + 256^{(0)}w_1$ ;

$\text{INT}(w')$  if the byte string  $w' = (w_1, \dots, w_t)$  is in  $B_t$ , then  $\text{INT}(w')$  is an integer  $W = 256^{(t-1)}w_1 + \dots + 256^{(0)}w_t$ ;

|| concatenation of byte strings A and C, i.e., if A in  $B_{n1}$ , C in  $B_{n2}$ ,  $A = (a_1, a_2, \dots, a_{n1})$  and  $C = (c_1, c_2, \dots, c_{n2})$ , then  $A||C = (a_1, a_2, \dots, a_{n1}, c_1, c_2, \dots, c_{n2})$  is an element of  $B_{(n1+n2)}$ ;

Byte representation of a point  $(X, Y)$ . If  $(X, Y)$  is an elliptic curve point then the byte representation of  $(X, Y)$  is a concatenation of the coordinates of this point  $X||Y$ ; the length of the byte representations of the coordinates X and Y is equal to the minimum possible length of the byte representation of the subgroup generator p.

#### [4. Mathematical definitions](#)

Suppose a prime number  $p > 3$  is given. Then, an elliptic curve E, defined over a finite prime field  $GF(p)$ , is the set of number pairs  $(x, y)$ , where x and y belong to  $F_p$ , satisfying the identity:

$$y^2 = x^3 + a * x + b \pmod{p},$$

where a, b belong to  $GF(p)$  and  $4 * a^3 + 27 * b^2$  is not congruent to zero modulo p.

An invariant of the elliptic curve is the value  $J(E)$ , satisfying the equality:

$$J(E) = \frac{4 * a^3}{4 * a^3 + 27 * b^2} \pmod{p},$$

Elliptic curve E coefficients a, b are defined in the following way using the invariant  $J(E)$ :

$$\begin{aligned} | a &= 3 * k \pmod{p}, \\ | \\ | b &= 2 * k \pmod{p}, \end{aligned}$$

$$J(E) \\ \text{where } k = \frac{J(E)}{1728 - J(E)} \pmod{p}, \quad J(E) \neq 0 \text{ or } 1728.$$

The pairs  $(x, y)$  satisfying the identity (1) are called "the elliptic curve E points"; x and y are called x- and y-coordinates of the point, correspondingly.

We will denote elliptic curve points as  $Q(x, y)$  or just Q. Two elliptic curve points are equal if their x- and y-coordinates are equal.

Smyshlyaev, et al.

Expires December 5, 2016

[Page 4]

On the set of all elliptic curve E points, we will define the addition operation, denoted by "+". For two arbitrary elliptic curve E points Q1 ( $x_1, y_1$ ) and Q2 ( $x_2, y_2$ ), we will consider several variants.

Suppose coordinates of points Q1 and Q2 satisfy the condition  $x_1 \neq x_2$ . In this case, their sum is defined as a point Q3 ( $x_3, y_3$ ), with coordinates defined by congruencies:

$$\begin{aligned} | x_3 &= \lambda^2 - x_1 - x_2 \pmod{p}, \\ | \\ | y_3 &= \lambda * (x_1 - x_3) - y_1 \pmod{p}, \\ &\quad y_1 - y_2 \\ \text{where } \lambda &= \frac{y_2 - y_1}{x_2 - x_1} \pmod{p}. \end{aligned}$$

If  $x_1 = x_2$  and  $y_1 = y_2 \neq 0$ , then we will define point Q3 coordinates in the following way:

$$\begin{aligned} | x_3 &= \lambda^2 - x_1 * 2 \pmod{p}, \\ | \\ | y_3 &= \lambda * (x_1 - x_3) - y_1 \pmod{p}, \\ &\quad 3 * x_1^2 + a \\ \text{where } \lambda &= \frac{y_1 * 2}{x_1 * 2} \pmod{p}. \end{aligned}$$

If  $x_1 = x_2$  and  $y_1 = -y_2 \pmod{p}$ , then the sum of points Q1 and Q2 is called a zero point 0, without determination of its x- and y-coordinates. In this case, point Q2 is called a negative of point Q1. For the zero point, the equalities hold:

$$0 + Q = Q + 0 = Q,$$

where Q is an arbitrary point of elliptic curve E.

A set of all points of elliptic curve E, including the zero point, forms a finite abelian (commutative) group of order m regarding the introduced addition operation. For m, the following inequalities hold:

$$p + 1 - 2 * \sqrt{p} \leq m \leq p + 1 + 2 * \sqrt{p}.$$

The point Q is called "a point of multiplicity k", or just "a multiple point of the elliptic curve E", if for some point P, the following equality holds:

Smyshlyaev, et al.

Expires December 5, 2016

[Page 5]

$$Q = P + \dots + P = k * P$$

-----  
k

## [5. Protocol description](#)

The protocol is used by subjects A and B that are commencing key establishment with password-based authentication.

### [5.1. Protocol parameters](#)

Various elliptic curves can be used in the protocol. For each elliptic curve supported by clients the following values must be defined:

- o the curve identifier ID\_ALG, that is a byte string of arbitrary length;
- o the point P, that is a generator point of the subgroup of order q of the curve;
- o the set of distinct curve points {Q\_1, Q\_2, ..., Q\_N} of order q, where the total number of points N is defined for protocol instance.

The method of generation of the points {P, Q\_1, Q\_2, ..., Q\_N} is described in [Section 6](#).

The protocol parameters that are used by subject A are the following:

1. The secret password value PW, which is a byte string that is uniformly randomly chosen from a subset of cardinality  $10^{10}$  or greater of the set B\_k, where k  $\geq 6$  is password length.
2. The list of curve identifiers supported by A.
3. Sets of points {Q\_1, Q\_2, ..., Q\_N}, corresponding to curves supported by A.
4. The C\_1^A counter, that tracks the total number of unsuccessful authentication trials in a row, and a value of CLim\_1 that stores the maximum possible number of such events.
5. The C\_2^A counter, that tracks the total number of unsuccessful authentication events during the period of usage of the specific PW, and a value of CLim\_2 that stores the maximum possible number of such events.

Smyshlyaev, et al.

Expires December 5, 2016

[Page 6]

6. The  $C_{3^A}$  counter, that tracks the total number of authentication events (successful and unsuccessful) during the period of usage of the specific PW, and a value of  $CLim_3$  that stores the maximum possible number of such events. The identifier  $ID_A$  of subject A (optional), a byte string of an arbitrary length.
7. The unique identifier  $ID_A$  of the subject A (optional, see. Note 2), which is a byte string of an arbitrary length.

The protocol parameters that are used by subject B are the following:

1. The values  $ind$  and  $salt$ , where  $ind$  is in  $\{1, \dots, N\}$ ,  $salt$  is in  $\{1, \dots, 2^{128-1}\}$ .

2. The point  $Q_{PW}$ , satisfying the following equation:

$$Q_{PW} = \text{int}(F(PW, salt, 2000)) * Q_{ind}.$$

It is possible that the point  $Q_{PW}$  is not stored and is calculated using  $PW$  in the beginning of the protocol. In that case B has to store  $PW$  and points  $Q_1, Q_2, \dots, Q_N$ .

3. The  $ID_{ALG}$  identifier of the elliptic curve used in the protocol.
4. The  $C_{1^B}$  counter, that tracks the total number of unsuccessful authentication trials in a row, and a value of  $CLim_1$  that stores the maximum possible number of such events.
5. The  $C_{2^B}$  counter, that tracks the total number of unsuccessful authentication events during the period of usage of the specific PW, and a value of  $CLim_2$  that stores the maximum possible number of such events.
6. The  $C_{3^B}$  counter, that tracks the total number of authentication events (successful and unsuccessful) during the period of usage of the specific PW, and a value of  $CLim_3$  that stores the maximum possible number of such events. The identifier  $ID_B$  of subject B (optional), a byte string of an arbitrary length.
7. The unique identifier  $ID_B$  of the subject B (optional, see. Note 2), which is a byte string of an arbitrary length.

## **5.2. Initial values of the protocol counters**

After the setup of a new password value  $PW$  the values of the counters must be assigned as follows:

- o  $C_{1^A} = C_{1^B} = CLim_1$ , where  $CLim_1$  is in  $\{3, \dots, 5\}$ ;

- o  $C_2^A = C_2^B = CLim_2$ , where  $CLim_2$  is in  $\{7, \dots, 20\}$ ;
- o  $C_3^A = C_3^B = CLim_3$ , where  $CLim_3$  is in  $\{10^3, 10^{3+1}, \dots, 10^5\}$ .

### 5.3. Protocol steps

The described protocol consists of the following steps:

1. If any of the counters  $C_1^A$ ,  $C_2^A$ ,  $C_3^A$  is equal to 0, A finishes the protocol with an error that informs of exceeding the number of trials that is controlled by the corresponding counter.
2. A decrements each of the counters  $C_1^A$ ,  $C_2^A$ ,  $C_3^A$  by 1, requests open authentication information from B and sends the  $ID_A$  identifier.
3. If any of the counters  $C_1^B$ ,  $C_2^B$ ,  $C_3^B$  is equal to 0, B finishes the protocol with an error that informs of exceeding the number of trials that is controlled by the corresponding counter.
4. B decrements each of the counters  $C_1^B$ ,  $C_2^B$ ,  $C_3^B$  by 1.
5. B sends the values of  $ind$ , salt and the  $ID_{ALG}$  identifier to A. B also can OPTIONALLY send the  $ID_B$  identifier to A. All following calculations are done by B in the elliptic curve group defined by the  $ID_{ALG}$  identifier.
6. A sets the curve defined by the received  $ID_{ALG}$  identifier as the used elliptic curve. All following calculations are done by A in this elliptic curve group.
7. A calculates the point  $Q_{PW^A} = \text{int}(F(PW, \text{salt}, 2000)) * Q_{ind}$ .
8. A chooses randomly (according to the uniform distribution) the value alpha, alpha is in  $\{1, \dots, q-1\}$ , and assigns  $z_A = 0$ .
9. A sends the value  $u_1 = \alpha * P - Q_{PW^A}$  to B.
10. After receiving  $u_1$ , B checks that  $u_1$  is in E. If it is not, B finishes with an error, considering the authentication process unsuccessful.
11. B calculates  $Q_B = u_1 + Q_{PW}$ , assigns  $z_B = 0$  and chooses randomly (according to the uniform distribution) the value betta, betta is in  $\{1, \dots, q-1\}$ .

12. If  $m/q \cdot Q_B = 0$ , B assigns  $Q_B = P$  and  $z_B = 1$ .
13. B calculates  $K_B = \text{HASH}((m/q \cdot \text{betta} \cdot (\text{mod } q)) \cdot Q_B)$ , where the input of a hash function is a little-endian representation of the obtained point (x-coordinate first, then y-coordinate).
14. B sends the value  $u_2 = \text{betta} \cdot P + Q_{PW}$  to A.
15. After receiving  $u_2$ , A checks that  $u_2$  is in E. If it is not, A finishes with an error, considering the authentication process unsuccessful.
16. A calculates  $Q_A = u_2 - Q_{PW} \cdot A$ .
17. If  $m/q \cdot Q_A = 0$ , then A assigns  $Q_A = P$  and  $z_A = 1$ .
18. A calculates  $K_A = \text{HASH}((m/q \cdot \alpha \cdot (\text{mod } q)) \cdot Q_A)$ , where the input of a hash function is a little-endian representation of the obtained point (x-coordinate first, then y-coordinate).
19. A calculates  $\text{MAC}_A = \text{HMAC}(K_A, 0x01 || ID_A || \text{ind} || \text{salt} || u_1 || u_2 || \text{DATA}_A)$ , where  $\text{DATA}_A$  is an optional string that is authenticated with  $\text{MAC}_A$  (if it is not used, then  $\text{DATA}_A$  is considered to be of zero length).
20. A sends  $(\text{DATA}_A || \text{MAC}_A)$  to B.
21. B checks that the values  $\text{MAC}_A$  and  $\text{HMAC}(K_B, 0x01 || ID_A || \text{ind} || \text{salt} || u_1 || u_2 || \text{DATA}_A)$  are equal. If they are not, it finishes with an error, considering the authentication process unsuccessful.
22. If  $z_B = 1$ , B finishes, considering the authentication process unsuccessful.
23. B sets the value of  $C_1 \cdot B$  to  $\text{CLim}_1$  and increases  $C_2 \cdot B$  by 1.
24. B calculates  $\text{MAC}_B = \text{HMAC}(K_B, 0x02 || ID_B || \text{ind} || \text{salt} || u_1 || u_2 || \text{DATA}_A || \text{DATA}_B)$ , where  $\text{DATA}_B$  is an optional string that is authenticated with  $\text{MAC}_B$  (if it is not used, then  $\text{DATA}_B$  is considered to be of zero length).
25. B sends  $(\text{DATA}_B || \text{MAC}_B)$  to A.
26. A checks that the values  $\text{MAC}_B$  and  $\text{HMAC}(K_A, 0x02 || ID_B || \text{ind} || \text{salt} || u_1 || u_2 || \text{DATA}_A || \text{DATA}_B)$  are equal. If they are not, it finishes with an error, considering the authentication process unsuccessful.

27. If  $z_A = 1$ , A finishes, considering the authentication process unsuccessful.
28. A sets the value of  $C_1^A$  to  $CLim_1$  and increases  $C_2^A$  by 1.

After the successful finish of the procedure the subjects A and B are mutually authenticated and each subject has an explicitly authenticated value of  $K = K_A = K_B$ .

Note:

1. In the case where the interaction process can be initiated by any subject (client or server) the  $ID_A$  and  $ID_B$  options MUST be used and the receiver MUST check that the identifier he had received is not equal to his own, otherwise, it finishes the protocol. If an optional parameter  $ID_A$  (or  $ID_B$ ) is not used in the protocol, it SHOULD be considered equal to a fixed byte string (zero-length string is allowed) defined by a specific implementation.
2. The  $ind$ ,  $ID_A$ ,  $ID_B$  and salt parameters can be agreed in advance. If some parameter is agreed in advance, it is possible not to send it during a corresponding step. Nevertheless, all parameters MUST be used as corresponding inputs to HMAC function during stages 19, 21, 24 and 26.
3. The  $ID_ALG$  parameter can be fixed or agreed in advance.
4. Continuation of protocol interaction in case of any of the counters  $C_1^A$ ,  $C_1^B$  being equal to zero MAY be done without changing password. In this case these counters can be used for protection against denial-of-service attacks. For example, continuation of interaction can be allowed after a certain delay.
5. Continuation of protocol interaction in case of any of the counters  $C_2^A$ ,  $C_2^B$ ,  $C_3^A$ ,  $C_3^B$  being equal to zero MUST be done only after changing password.

## **6. Construction of points $Q_1, \dots, Q_N$**

This section provides an example of possible algorithm for generation of each point  $Q_i$  in the set  $\{Q_1, \dots, Q_N\}$  that corresponds to the given elliptic curve E.

The algorithm is based on choosing points with coordinates with a known preimages of a cryptographic hash function H, which is the GOST R 34.11-2012 hash function (see [[RFC6986](#)]) with 256-bit output, if  $2^{254} < q < 2^{256}$ , and the GOST R 34.11-2012 hash function (see [[RFC6986](#)]) with 512-bit output, if  $2^{508} < q < 2^{512}$ .

The algorithm consists of the following steps:

1. Choose an arbitrary SEED value with length of 32 bytes or more.
2. Calculate  $X = \text{INT}(\text{H}(\text{SEED})) \bmod p$ .
3. Check that the value of  $X^3 + aX + b$  is a quadratic residue in the field  $F_p$ . If it is not, return to Step 1.
4. Choose the value of  $Y$  arbitrarily from the set  $\{+\sqrt{A}, -\sqrt{A}\}$ , where  $A = X^3 + aX + b$ . Here  $\sqrt{A}$  is an element of  $F_p$ , for which  $(\sqrt{A})^2 = A \bmod p$ .
5. Check that for point  $Q = (X, Y)$  the following relations hold:  $Q \neq 0$  and  $q*Q = 0$ . If they do not, return to Step 1.

With the defined algorithm for any elliptic curve  $E$  point sets  $\{Q_1, \dots, Q_N\}$  are constructed. Constructed points in one set MUST have distinct x-coordinates.

**Note:** The knowledge of hash function preimage prevents knowledge of the multiplicity of any point related to generator point  $P$ . It is of primary importance, because such a knowledge could be used to implement an attack against protocol with exhaustive search of password.

## **7. Acknowledgments**

We thank Lolita Sonina, Georgy Borodin, Sergei Agafin and Ekaterina Smyshlyayeva for their careful readings and useful comments.

## **8. Security Considerations**

Any cryptographic algorithms, particularly HASH function and HMAC function, that are used in the SESPAKE protocol MUST be carefully designed and MUST be able to withstand all known types of cryptanalytic attack.

It is RECOMMENDED that the HASH function satisfies the following condition:

$\text{hashlen} \leq \log_2(q) + 4$ , where  $\text{hashlen}$  is the the lenghts of the HASH function output.

The output lenghts of hash functions that are used in the SESPAKE protocol is RECOMMENDED to be greater or equal to 256 bits.

The points  $Q_1, Q_2, \dots, Q_3$  and  $P$  must be chosen in such a way that they are provable pseudorandomness. As a practical matter, this

means that the algorithm for generation of each point  $Q_i$  in the set  $\{Q_1, \dots, Q_N\}$  (see [Section 6](#)) ensures that multiplicity of any point under any other point is unknown.

## [Appendix A.](#) Test examples for GOST-based protocol implementation

The following test examples are made for the protocol implementation that is based on the Russian national standards GOST R 34.10-2012 [[GOST3410-2012](#)] and GOST R 34.11-2012 [[GOST3411-2012](#)]. The English versions of these standards can be found in [[RFC7091](#)] and [[RFC6986](#)].

### [A.1.](#) Examples of points

There are three points (Q\_1, Q\_2, Q\_3) for each of the elliptic curves below. This points were constructed using the method described in [Section 6](#), where the GOST R 34.11-2012 hash function (see [[RFC6986](#)]) with 256-bit output is used if  $2^{254} < q < 2^{256}$  and the GOST R 34.11-2012 hash function (see [[RFC6986](#)]) with 512-bit output is used if  $2^{508} < q < 2^{512}$ .

The same method should be used for constructing, if necessary, additional points. Each of the points complies with the GOST R 34.10-2012 [[GOST3410-2012](#)] standard and is represented by a pair of (X, Y) coordinates in the canonical form and by a pair of (U, V) coordinates in the twisted Edward form in accordance with the document [[RFC7836](#)] for the curves that have the equivalent representation in this form. There is a SEED value for each point, by which it was generated.

## A.2. Test examples

This protocol implementation uses the GOST R 34.11-2012 hash function (see [[RFC6986](#)]) with 256-bit output as the H function and the HMAC\_GOSTR3411\_2012\_512 function defined in [[RFC7836](#)] as a PRF function for the F function. The parameter len is considered equal to 256, if  $2^{254} < q < 2^{256}$ , and equal to 512, if  $2^{508} < q < 2^{512}$ .

The test examples for one of the three points of each curve in [Appendix A.1](#) of this document are given below.

### A.2.1 Curveid-GostR3410-2001-CryptoPro-A-ParamSet

The input protocol parameters in this example take the following values:

```

N= 3
ind= 1
ID_A:
  00 00 00 00
ID_B:
  00 00 00 00
PW:
  31 32 33 34 35 36 ('123456')
salt:
  29 23 be 84 e1 6c d6 ae 52 90 49 f1 f1 bb e9 eb
Q_ind:
  X= 0xa33ce065b0c23e1d3d026a206f8a1f8747ed1cd92a665bf85198cdb10ac90a5c
  Y= 0xb00d0dc0733883f05de9f55fd711f55998f5508cc40bead80c913b4d5b533667

```

The function F (PW, salt, 2000) takes the following values:

```

F(PW,salt,2000):
  bd 04 67 3f 71 49 b1 8e 98 15 5b d1 e2 72 4e 71
  d0 09 9a a2 51 74 f7 92 d3 32 6c 6f 18 12 70 67

```

The coordinates of the point Q\_PW are:

```

X= 0x9d339b3396ae4a816388a14c79ab3a8dd495fa4c53f0d4076579022ef2aaeb68
Y= 0xdad91482e208590fd316bf959480f5ec2c17463ec8fc8f63030649b452cddda8

```

During the calculation of the message u\_1 on the subject A the parameter alpha, the point alpha\*P and the message u\_1 take the following values:  
alpha=0xfcdb45d1f2538097d5a031fa68bbb43c84d12b3de47b7061c0d5e24993e0c87  
alphaP:

```

X= 0x24538e096781b9d53316c342ae5bbd49ccfb2db627c3659175bc4fa9d95b4618
Y= 0xf6e39a7490ae0ac449f5abe7e2135697c582daf3a038c40a05e6e8be3e466a2b

```

```

u_1:
  X= 0xcf73b30dd577369fb98e2a93d6d98d7450f9ceef2bada1e3dcb8bb1016dff1e1
  Y= 0x1cf05014caedb1635120b30e0a445060b8f1cca52965cf83c4838d554ca4e2

```

Smyshlyaev, et al.

Expires December 5, 2016

[Page 19]

During processing a message  $u_1$ , calculation the  $K_B$  key and the message  $u_2$  on the subject B the parameters betta, src,  $K_B = \text{HASH}(\text{src})$ ,  $\text{betta}^*P$  and  $u_2$  take the following values:

$\text{betta}=0xf2144faddc497d9ef6324912fd367840ee509a2032aedb1c0a890d133b45f596$
