The Security Evaluated Standardized Password Authenticated Key Exchange
(SESPAKE) Protocol
[draft-smyshlyaev-sespake-15](#)

Abstract

This document specifies the Security Evaluated Standardized Password Authenticated Key Exchange (SESPAKE) protocol. The SESPAKE protocol provides password authenticated key exchange for usage in the systems for protection of sensitive information. The security proofs of the protocol were made for the case of an active adversary in the channel, including MitM attacks and attacks based on the impersonation of one of the subjects.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on June 25, 2017.

[1.](#) Introduction

The current document contains the description of the password authenticated key exchange protocol SESPAKE (security evaluated standardized password authenticated key exchange) for usage in the systems for protection of sensitive information. The protocol is intended to use for establishment of keys that are then used for organization of secure channel for protection of sensitive information. The security proofs of the protocol were made for the case of an active adversary in the channel, including MitM attacks and attacks based on the impersonation of one of the subjects.

[2.](#) Conventions Used in This Document

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [[RFC2119](#)].

3. Notations

This document uses the following parameters of elliptic curves in accordance with [\[RFC6090\]](#):

- E an elliptic curve defined over a finite prime field $GF(p)$, where $p > 3$;
- p the characteristic of the underlying prime field;
- a, b the coefficients of the equation of the elliptic curve in the canonical form;
- m the elliptic curve group order;
- q the elliptic curve subgroup order;
- P a generator of the subgroup of order q;
- X, Y the coordinates of the elliptic curve point in the canonical form;
- O zero point (point of infinity) of the elliptic curve.

This memo uses the following functions:

- HASH the underlying hash function;
- HMAC the function for calculating a message authentication code, based on a HASH function in accordance with [\[RFC2104\]](#);
- $F(PW, salt, n)$ the value of the function $PBKDF2(PW, salt, n, len)$, where $PBKDF2(PW, salt, n, len)$ is calculated according to [\[RFC2898\]](#) The parameter len is considered equal to minimal integer that is a multiple of 8 and satisfies the following condition:
 $len \geq \text{floor}(\log_2(q))$.

This document uses the following terms and definitions for the sets and operations on the elements of these sets

- B_n the set of byte strings of size n, $n \geq 0$, for $n = 0$ the B_n set consists of a single empty string of size 0; if b is an element of B_n , then $b = (b_1, \dots, b_n)$, where $b_1, \dots, b_n$ are elements of $\{0, \dots, 255\}$;
- $||$ concatenation of byte strings A and C, i.e., if A in B_{n1} , C in B_{n2} , $A = (a_1, a_2, \dots, a_{n1})$ and $C = (c_1, c_2, \dots, c_{n2})$,

then $A||C = (a_1, a_2, \dots, a_n, c_1, c_2, \dots, c_n)$ is an element of $B_{(n+1)}$;

$\text{int}(A)$ for the byte string $A = (a_1, \dots, a_n)$ in B_n an integer $\text{int}(A) = 256^{(n-1)}a_n + \dots + 256^{(0)}a_1$;

$\text{bytes}_n(X)$ the byte string A in B_n such that $\text{int}(A) = X$, where X is integer, $0 \leq X < 256^n$;

$\text{BYTES}(Q)$ for Q in E , the byte string $\text{bytes}_n(X) || \text{bytes}_n(Y)$, where X, Y are standard Weierstrass coordinates of point Q and $n = \text{ceil}(\log_{\{256\}}(p))$.

4. Protocol Description

The main point of the SESPAKE protocol is that parties sharing a weak key (a password) generate a strong common key. The active adversary who has an access to a channel is not able to obtain any information that can be used to find a key in offline mode, i.e. without interaction with legitimate participants.

The protocol is used by the subjects A (client) and B (server) that share some secret parameter that was established in an out-of-band mechanism: a client is a participant who stores a password as a secret parameter and a server is a participant who stores a password-based computed point of the elliptic curve.

The SESPAKE protocol consists of two steps: the key agreement step and the key confirmation step. During the first step (the key agreement step) the parties exchange keys using Diffie-Hellman with public components masked by an element that depends on the password - one of the predefined elliptic curve points multiplied by the password-based coefficient. This approach provides an implicit key authentication, which means that after this step one party is assured that no other party aside from a specifically identified second party may gain access to the generated secret key. During the second step (the key confirmation step) the parties exchange strings that strongly depend on the generated key. After this step the parties are assured that a legitimate party and no one else actually has possession of the secret key.

To protect against online guessing attacks the failed connections counters were introduced in the SESPAKE protocol. There is also a special way of a small order point processing and a mechanism that provides a reflection attack protection by using different operations for different sides.

4.1. Protocol Parameters

Various elliptic curves can be used in the protocol. For each elliptic curve supported by clients the following values MUST be defined:

- o the protocol parameters identifier ID_ALG (which can also define a HASH function, PRF used in PBKDF2 function, etc.), that is a byte string of an arbitrary length;
- o the point P, that is a generator point of the subgroup of order q of the curve;
- o the set of distinct curve points $\{Q_1, Q_2, \dots, Q_N\}$ of order q, where the total number of points N is defined for protocol instance.

The method of generation of the points $\{P, Q_1, Q_2, \dots, Q_N\}$ is described in [Section 5](#).

The protocol parameters that are used by subject A are the following:

1. The secret password value PW, which is a byte string that is uniformly randomly chosen from a subset of cardinality 10^{10} or greater of the set B_k , where $k \geq 6$ is password length.
2. The list of curve identifiers supported by A.
3. Sets of points $\{Q_1, Q_2, \dots, Q_N\}$, corresponding to curves supported by A.
4. The C_1^A counter, that tracks the total number of unsuccessful authentication trials in a row, and a value of CLim_1 that stores the maximum possible number of such events.
5. The C_2^A counter, that tracks the total number of unsuccessful authentication events during the period of usage of the specific PW, and a value of CLim_2 that stores the maximum possible number of such events.
6. The C_3^A counter, that tracks the total number of authentication events (successful and unsuccessful) during the period of usage of the specific PW, and a value of CLim_3 that stores the maximum possible number of such events.
7. The unique identifier ID_A of the subject A (OPTIONAL), which is a byte string of an arbitrary length.

The protocol parameters that are used by subject B are the following:

1. The values ind and $salt$, where ind is in $\{1, \dots, N\}$, $salt$ is in $\{1, \dots, 2^{128}-1\}$.
2. The point Q_{PW} , satisfying the following equation:

$$Q_{PW} = \text{int} (F (PW, salt, 2000)) * Q_{ind}.$$

It is possible that the point Q_{PW} is not stored and is calculated using PW in the beginning of the protocol. In that case B has to store PW and points $Q_1, Q_2, \dots, Q_N$.

3. The ID_{ALG} identifier.
4. The C_1^A counter, that tracks the total number of unsuccessful authentication trials in a row, and a value of $CLim_1$ that stores the maximum possible number of such events.
5. The C_2^A counter, that tracks the total number of unsuccessful authentication events during the period of usage of the specific PW , and a value of $CLim_2$ that stores the maximum possible number of such events.
6. The C_3^A counter, that tracks the total number of authentication events (successful and unsuccessful) during the period of usage of the specific PW , and a value of $CLim_3$ that stores the maximum possible number of such events.
7. The unique identifier ID_B of the subject B (OPTIONAL), which is a byte string of an arbitrary length.

4.2. Initial Values of the Protocol Counters

After the setup of a new password value PW the values of the counters MUST be assigned as follows:

- o $C_1^A = C_1^B = CLim_1$, where $CLim_1$ is in $\{3, \dots, 5\}$;
- o $C_2^A = C_2^B = CLim_2$, where $CLim_2$ is in $\{7, \dots, 20\}$;
- o $C_3^A = C_3^B = CLim_3$, where $CLim_3$ is in $\{10^3, 10^3+1, \dots, 10^5\}$.

4.3. Protocol Steps

The basic SESPAKE steps are shown in the scheme below:

+-----+-----+-----+-----+

A [A_ID, PW]		B [B_ID, Q_PW , ind, salt]
if C_1^A or C_2^A or $C_3^A = 0 \implies$ QUIT		
decrement C_1^A , C_2^A , C_3^A by 1	A_ID --->	if C_1^B or C_2^B or $C_3^B = 0 \implies$ QUIT
$z_A = 0$	<--- ID_ALG, B_ID (OPTIONAL), ind, salt	decrement C_1^B , C_2^B , C_3^B by 1
$Q_{PW}^A = \text{int}(F(PW, \text{salt}, 2000)) * Q_{ind}$		
choose alpha randomly from $\{1, \dots, q-1\}$		
$u_1 = \alpha * P - Q_{PW}^A$	u_1 --->	if u_1 not in E $\implies$ QUIT
		$z_B = 0$
		$Q_B = u_1 + Q_{PW}$
		choose betta randomly from $\{1, \dots, q-1\}$
		if $m/q * Q_B = 0 \implies Q_B = \text{betta} * P, z_B = 1$
		$K_B = \text{HASH}(\text{BYTES}((m/q * \text{betta} * (\text{mod } q)) * Q_B))$
if u_2 not in E $\implies$ QUIT	<--- u_2	$u_2 = \text{betta} * P + Q_{PW}$
$Q_A = u_2 - Q_{PW}^A$		
if $m/q * Q_A = 0 \implies Q_A = \alpha * P, z_A = 1$		
$K_A = \text{HASH}(\text{BYTES}((m/q * \alpha * (\text{mod } q)) * Q_A))$		

	U_1 = BYTES(u_1), U_2 =

	if z_A = 1 ==> QUIT		
	C_1^A = CLim_1,		
	increment C_2^A by 1		
+-----+	+-----+	+-----+	+-----+

Table 1: SESPAKE protocol steps

The full description of the protocol consists of the following steps:

1. If any of the counters C_1^A , C_2^A , C_3^A is equal to 0, A finishes the protocol with an error that informs of exceeding the number of trials that is controlled by the corresponding counter.
2. A decrements each of the counters C_1^A , C_2^A , C_3^A by 1, requests open authentication information from B and sends the ID_A identifier.
3. If any of the counters C_1^B , C_2^B , C_3^B is equal to 0, B finishes the protocol with an error that informs of exceeding

the number of trials that is controlled by the corresponding counter.

4. B decrements each of the counters C_1^B , C_2^B , C_3^B by 1.
5. B sends the values of ind , $salt$ and the ID_ALG identifier to A. B also can OPTIONALLY send the ID_B identifier to A. All following calculations are done by B in the elliptic curve group defined by the ID_ALG identifier.
6. A sets the curve defined by the received ID_ALG identifier as the used elliptic curve. All following calculations are done by A in this elliptic curve group.
7. A calculates the point $Q_{PW^A} = \text{int}(F(PW, salt, 2000)) * Q_{ind}$.
8. A chooses randomly (according to the uniform distribution) the value α , α is in $\{1, \dots, q-1\}$, and assigns $z_A = 0$.
9. A sends the value $u_1 = \alpha * P - Q_{PW^A}$ to B.
10. After receiving u_1 , B checks that u_1 is in E . If it is not, B finishes with an error, considering the authentication process unsuccessful.
11. B calculates $Q_B = u_1 + Q_{PW}$, assigns $z_B = 0$ and chooses randomly (according to the uniform distribution) the value β , β is in $\{1, \dots, q-1\}$.
12. If $m/q * Q_B = 0$, B assigns $Q_B = \beta * P$ and $z_B = 1$.
13. B calculates $K_B = \text{HASH}(\text{BYTES}((m/q * \beta * (\text{mod } q)) * Q_B))$.
14. B sends the value $u_2 = \beta * P + Q_{PW}$ to A.
15. After receiving u_2 , A checks that u_2 is in E . If it is not, A finishes with an error, considering the authentication process unsuccessful.
16. A calculates $Q_A = u_2 - Q_{PW^A}$.
17. If $m/q * Q_A = 0$, then A assigns $Q_A = \alpha * P$ and $z_A = 1$.
18. A calculates $K_A = \text{HASH}(\text{BYTES}((m/q * \alpha * (\text{mod } q)) * Q_A))$.
19. A calculates $U_1 = \text{BYTES}(u_1)$, $U_2 = \text{BYTES}(u_2)$.

20. A calculates $MAC_A = HMAC(K_A, 0x01 || ID_A || ind || salt || U_1 || U_2 || ID_ALG (OPTIONAL) || DATA_A)$, where $DATA_A$ is an OPTIONAL string that is authenticated with MAC_A (if it is not used, then $DATA_A$ is considered to be of zero length).
21. A sends $DATA_A$, MAC_A to B.
22. B calculates $U_1 = BYTES(u_1)$, $U_2 = BYTES(u_2)$.
23. B checks that the values MAC_A and $HMAC(K_B, 0x01 || ID_A || ind || salt || U_1 || U_2 || ID_ALG (OPTIONAL) || DATA_A)$ are equal. If they are not, it finishes with an error, considering the authentication process unsuccessful.
24. If $z_B = 1$, B finishes, considering the authentication process unsuccessful.
25. B sets the value of C_1^A to $CLim_1$ and increments C_2^A by 1.
26. B calculates $MAC_B = HMAC(K_B, 0x02 || ID_B || ind || salt || U_1 || U_2 || ID_ALG (OPTIONAL) || DATA_A || DATA_B)$, where $DATA_B$ is an OPTIONAL string that is authenticated with MAC_B (if it is not used, then $DATA_B$ is considered to be of zero length).
27. B sends $DATA_B$, MAC_B to A.
28. A checks that the values MAC_B and $HMAC(K_A, 0x02 || ID_B || ind || salt || U_1 || U_2 || ID_ALG (OPTIONAL) || DATA_A || DATA_B)$ are equal. If they are not, it finishes with an error, considering the authentication process unsuccessful.
29. If $z_A = 1$, A finishes, considering the authentication process unsuccessful.
30. A sets the value of C_1^A to $CLim_1$ and increments C_2^A by 1.

After the successful finish of the procedure the subjects A and B are mutually authenticated and each subject has an explicitly authenticated value of $K = K_A = K_B$.

N o t e s :

1. In the case when the interaction process can be initiated by any subject (client or server) the ID_A and ID_B options MUST be used and the receiver MUST check that the identifier he had received is not equal to his own, otherwise, it finishes the protocol. If an OPTIONAL parameter ID_A (or ID_B) is not used in the protocol,

it SHOULD be considered equal to a fixed byte string (zero-length string is allowed) defined by a specific implementation.

2. The `ind`, `ID_A`, `ID_B` and `salt` parameters can be agreed in advance. If some parameter is agreed in advance, it is possible not to send it during a corresponding step. Nevertheless, all parameters MUST be used as corresponding inputs to HMAC function during stages 20, 23, 26 and 28.
3. The `ID_ALG` parameter can be fixed or agreed in advance.
4. The `ID_ALG` parameter is RECOMMENDED to be used in HMAC during stages 20, 23, 26 and 28.
5. Continuation of protocol interaction in case of any of the counters C_1^A , C_1^B being equal to zero MAY be done without changing password. In this case these counters can be used for protection against denial-of-service attacks. For example, continuation of interaction can be allowed after a certain delay.
6. Continuation of protocol interaction in case of any of the counters C_2^A , C_3^A , C_2^B , C_3^B being equal to zero MUST be done only after changing password.
7. It is RECOMMENDED that during the stages 9 and 14 the points u_1 and u_2 are sent in a non-compressed format (`BYTES(u_1)` and `BYTES(u_2)`). However, the point compression MAY be used.
8. The use of several Q points can reinforce the independence of the data streams in case of working with several applications, when, for example, two high-level protocols can use two different points. However, the use of more than one point is OPTIONAL.

5. Construction of Points $Q_1, \dots, Q_N$

This section provides an example of possible algorithm for generation of each point Q_i in the set $\{Q_1, \dots, Q_N\}$ that corresponds to the given elliptic curve E .

The algorithm is based on choosing points with coordinates with a known preimages of a cryptographic hash function H , which is the GOST R 34.11-2012 hash function (see [\[RFC6986\]](#)) with 256-bit output, if $2^{254} < q < 2^{256}$, and the GOST R 34.11-2012 hash function (see [\[RFC6986\]](#)) with 512-bit output, if $2^{508} < q < 2^{512}$.

The algorithm consists of the following steps:

1. Set $i = 1$, $SEED = 0$, $s = 4$ or more.

2. Calculate $X = \text{int}(\text{HASH}(\text{BYTES}(P) || \text{bytes_s}(\text{SEED}))) \bmod p$.
3. Check that the value of $X^3 + aX + b$ is a quadratic residue in the field F_p . If it is not, set $\text{SEED} = \text{SEED} + 1$ and return to Step 2.
4. Choose the value of $Y = \min\{r_1, r_2\}$, where r_1, r_2 from $\{0, 1, \dots, p-1\}$ such that $r_1 \neq r_2$ and $r_1^2 = r_2^2 = R \bmod p$ for $R = X^3 + aX + b$.
5. Check that for point $Q = (X, Y)$ the following relations hold: $Q \neq 0$ and $q \cdot Q = 0$. If they do, go to Step 6, if not, set $\text{SEED} = \text{SEED} + 1$ and return to Step 2.
6. Set $Q_i = Q$. If $i < N$, then set $i = i+1$ and go to Step 2, else FINISH.

With the defined algorithm for any elliptic curve E point sets $\{Q_1, \dots, Q_N\}$ are constructed. Constructed points in one set MUST have distinct X-coordinates.

N o t e : The knowledge of a hash function preimage prevents knowledge of the multiplicity of any point related to generator point P . It is of primary importance, because such a knowledge could be used to implement an attack against protocol with exhaustive search of password.

6. Acknowledgments

We thank Lolita Sonina, Georgiy Borodin, Sergey Agafin and Ekaterina Smyshlyaeva for their careful readings and useful comments.

7. Security Considerations

Any cryptographic algorithms, particularly HASH function and HMAC function, that are used in the SESPAKE protocol MUST be carefully designed and MUST be able to withstand all known types of cryptanalytic attack.

It is RECOMMENDED that the HASH function satisfies the following condition:

$\text{hashlen} \leq \log_2(q) + 4$, where hashlen is the lengths of the HASH function output.

The output length of hash functions that are used in the SESPAKE protocol is RECOMMENDED to be greater or equal to 256 bits.

The points $Q_1, Q_2, \dots, Q_N$ and P MUST be chosen in such a way that they are provable pseudorandom. As a practical matter, this means that the algorithm for generation of each point Q_i in the set $\{Q_1, \dots, Q_N\}$ (see [Section 5](#)) ensures that multiplicity of any point under any other point is unknown.

For a certain ID_ALG using $N = 1$ is RECOMMENDED.

Note: The exact adversary models, which have been considered during the security evaluation, can be found in the paper [\[SESPAKE-SECURITY\]](#), containing the security proofs.

Appendix A. Test Examples for GOST-based Protocol Implementation

The following test examples are made for the protocol implementation that is based on the Russian national standards GOST R 34.10-2012 [[GOST3410-2012](#)] and GOST R 34.11-2012 [[GOST3411-2012](#)]. The English versions of these standards can be found in [[RFC7091](#)] and [[RFC6986](#)].

A.1. Examples of Points

There is one point Q_1 for each of the elliptic curves below. This points were constructed using the method described in [Section 5](#), in case when $N = 1$, where the GOST R 34.11-2012 hash function (see [[RFC6986](#)]) with 256-bit output is used if $2^{254} < q < 2^{256}$, the GOST R 34.11-2012 hash function (see [[RFC6986](#)]) with 512-bit output is used if $2^{508} < q < 2^{512}$.

Each of the points complies with the GOST R 34.10-2012 [[GOST3410-2012](#)] standard and is represented by a pair of (X, Y) coordinates in the canonical form and by a pair of (U, V) coordinates in the twisted Edwards form in accordance with the document [[RFC7836](#)] for the curves that have the equivalent representation in this form. There is a SEED value for each point, by which it was generated.

A.2. Test Examples of SESPAKE

This protocol implementation uses the GOST R 34.11-2012 hash function (see [RFC6986]) with 256-bit output as the H function and the HMAC_GOSTR3411_2012_512 function defined in [RFC7836] as a PRF function for the F function. The parameter len is considered equal to 256, if $2^{254} < q < 2^{256}$, and equal to 512, if $2^{508} < q < 2^{512}$.

The test examples for the point of each curve in [Appendix A.1](#) are given below.

A.2.1 Curve id-GostR3410-2001-CryptoPro-A-ParamSet

The input protocol parameters in this example take the following values:

N = 1

ind = 1

ID_A:

```
00 00 00 00
```

ID_B:

```
00 00 00 00
```

PW:

```
31 32 33 34 35 36 ('123456')
```

salt:

```
29 23 BE 84 E1 6C D6 AE 52 90 49 F1 F1 BB E9 EB
```

Q_ind:

```
X = 0xA69D51CAF1A309FA9E9B66187759B0174C274E080356F23CFCBFE84D396AD7BB
```

```
Y = 0x5D26F29ECC2E9AC0404DCF7986FA55FE94986362170F54B9616426A659786DAC
```

The function F (PW, salt, 2000) takes the following values:

F(PW, salt, 2000):

```
BD 04 67 3F 71 49 B1 8E 98 15 5B D1 E2 72 4E 71
```

```
D0 09 9A A2 51 74 F7 92 D3 32 6C 6F 18 12 70 67
```

The coordinates of the point Q_PW are:

```
X = 0x59495655D1E7C7424C622485F575CCF121F3122D274101E8AB734CC9C9A9B45E
```

```
Y = 0x48D1C311D33C9B701F3B03618562A4A07A044E3AF31E3999E67B487778B53C62
```

During the calculation of the message u_1 on the subject A the parameter alpha, the point alpha*P and the message u_1 take the following values:

alpha=0x1F2538097D5A031FA68BBB43C84D12B3DE47B7061C0D5E24993E0C873CDBA6B3

alpha*P:

```

```

The message MAC_B=HMAC (K_B, 0x02 || ID_B || ind || salt || u_1 || u_2)
from the subject B takes the following value:

MAC_B:

```
A2 92 8A 5C F6 20 BB C4 90 0D E4 03 F7 FC 59 A5
E9 80 B6 8B E0 46 D0 B5 D9 B4 AE 6A BF A8 0B D6
```

[A.2.7 Curve id-tc26-gost-3410-2012-512-paramSetC](#)

The input protocol parameters in this example take the following values:

N = 1

ind = 1

ID_A:

```
00 00 00 00
```

ID_B:

```
00 00 00 00
```

PW:

```
31 32 33 34 35 36 ('123456')
```

salt:

```
