Using GOST ciphers in ESP and IKEv2
draft-smyslov-esp-gost-08

Abstract

This document defines a set of encryption transforms for use in the Encapsulating Security Payload (ESP) and in the Internet Key Exchange version 2 (IKEv2) protocols. The transforms are based on Russian cryptographic standard algorithms (GOST) in a Multilinear Galois Mode (MGM).

This specification is developed to facilitate implementations that wish to support the GOST algorithms. This document does not imply IETF endorsement of the cryptographic algorithms used in this document.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <https://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on June 4, 2022.

1. Introduction

This document defines four transforms for the Encapsulating Security Payload protocol (ESP) [[RFC4303](#)] and for the Internet Key Exchange protocol version 2 (IKEv2) [[RFC7296](#)]. These document is based on Russian Standard [[GOST-ESP](#)], which describes how Russian cryptographic standard algorithms are used in ESP and IKEv2.

Transforms defined in this document are based on two block ciphers from Russian cryptographic standard algorithms (often called "GOST" algorithms) - "Kuznyechik" [[GOST3412-2015](#)][[RFC7801](#)] and "Magma" [[GOST3412-2015](#)][[RFC8891](#)] in Multilinear Galois Mode (MGM) [[GOST-MGM](#)][[RFC9058](#)]. These transforms provide Authenticated Encryption with Associated Data (AEAD). An external re-keying mechanism, described in [[RFC8645](#)] is also used in these transforms to limit load on session keys.

Smyslov

[Page 2]

This specification is developed to facilitate implementations that wish to support the GOST algorithms. This document does not imply IETF endorsement of the cryptographic algorithms used in this document.

2. Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [BCP 14](#) [[RFC2119](#)] [[RFC8174](#)] when, and only when, they appear in all capitals, as shown here.

3. Overview

Russian cryptographic standard algorithms, often referred as "GOST" algorithms, constitute a set of cryptographic algorithms of different types - ciphers, hash functions, digital signatures etc. In particular, Russian cryptographic standard [[GOST3412-2015](#)] defines two block ciphers - "Kuznyechik" (also defined in [[RFC7801](#)]) and "Magma" (also defined in [[RFC8891](#)]). Both ciphers use 256-bit key. "Kuznyechik" has a block size of 128 bits, while "Magma" has a 64-bit block.

Multilinear Galois Mode (MGM) is an AEAD mode defined in [[GOST-MGM](#)][[RFC9058](#)]. It is claimed to provide defense against some attacks on well-known AEAD modes, like Galois Counter Mode (GCM).

[[RFC8645](#)] defines mechanisms that can be used to limit the number of times any particular session key is used. One of these mechanisms, called external re-keying with tree-based construction (defined in [Section 5.2.3 of \[RFC8645\]](#)), is used in the defined transforms. For the purpose of deriving subordinate keys a Key Derivation Function (KDF) KDF_GOSTR3411_2012_256 defined in [Section 4.5 of \[RFC7836\]](#), is used. This KDF is based on an HMAC [[RFC2104](#)] in a combination with a Russian GOST hash function defined in Russian cryptographic standard [[GOST3411-2012](#)] (also defined in [[RFC6986](#)]).

4. Transforms Description

This document defines four transforms for use in ESP and IKEv2. All of them use MGM mode of operation with tree-based external re-keying. The transforms differ in underlying ciphers and in cryptographic services they provide.

- o ENCR_KUZYNECHIK_MGM_KTREE (Transform ID 32) is an AEAD transform based on "Kuznyechik" algorithm; it provides confidentiality and message authentication and thus can be used both in ESP and IKEv2

Smyslov

Expires June 4, 2022

[Page 3]

- o ENCR_MAGMA_MGM_KTREE (Transform ID 33) is an AEAD transform based on "Magma" algorithm; it provides confidentiality and message authentication and thus can be used both in ESP and IKEv2
- o ENCR_KUZNYECHIK_MGM_MAC_KTREE (Transform ID 34) is a MAC-only transform based on "Kuznyechik" algorithm; it provides no confidentiality and thus can only be used in ESP, but not in IKEv2
- o ENCR_MAGMA_MGM_MAC_KTREE (Transform ID 35) is a MAC-only transform based on "Magma" algorithm; it provides no confidentiality and thus can only be used in ESP, but not in IKEv2

4.1. Tree-based External Re-Keying

All four transforms use the same tree-based external re-keying mechanism. The idea is that the key that is provided for the transform (Child SA key derived from KEYMAT in case of ESP or SK_ei/SK_er in case of IKEv2) is not directly used to protect messages. Instead a tree of keys is derived using this key as a root. This tree may have several levels. The leaf keys are used for messages protection, while intermediate nodes keys are used to derive lower level keys (including leaf keys). See [Section 5.2.3 of \[RFC8645\]](#) for more details. This construction allows to protect a large amount of data, at the same time providing a bound on a number of times any particular key in the tree is used, thus defending from some side channel attacks.

The transforms defined in this document use three-level tree. The leaf key that protects a message is computed as follows:

$$K_{\text{msg}} = \text{KDF} (\text{KDF} (\text{KDF} (K, l_1, i_1), l_2, i_2), l_3, i_3)$$

where:

KDF (k, l, s) Key Derivation Function KDF_GOSTR3411_2012_256 defined in [Section 4.5 of \[RFC7836\]](#), which accepts three input parameters - a key (k), a label (l) and a seed (s) and provides a new key as an output;

K the key for the transform (ESP SA key derived from KEYMAT or SK_ei/SK_er in case of IKEv2);

l1, l2, l3 labels defined as 6 octet ASCII strings without null termination:

l1 = "level1"

l2 = "level2"

Smyslov

Expires June 4, 2022

[Page 4]

```
l3 = "level3"
```

`i1, i2, i3` parameters that determine which keys out of the tree are used on each level, altogether they determine a leaf key that is used for message protection; these parameters are two octet integers in network byte order;

This construction allows to generate up to 2^{16} keys on each level, but due to IV construction (see [Section 4.2](#)) the number of possible keys on the level 1 is limited to 2^8 . So, the total number of possible leaf keys generated from one SA key is 2^{40} .

This specification doesn't impose any requirements on the frequency the external re-keying takes place. It is expected that sending application will follow its own policy dictating how many times the keys on each level must be used.

[4.2.](#) Initialization Vector Format

Each message protected by the defined transforms MUST contain Initialization Vector (IV). The IV has a size of 64 bits and consists of the four fields, three of which are `i1`, `i2` and `i3` parameters that determine the particular leaf key this message was protected with (see [Section 4.1](#)), and the fourth is a counter, representing the message number for this key.

Figure 1: IV Format

where:

- o `i1` (1 octet), `i2` (2 octets), `i3` (2 octets) - parameters, determining the particular key used to protect this message; 2-octets parameters are integers in network byte order
- o `pnum` (3 octets) - message counter in network byte order for the leaf key protecting this message; up to 2^{24} messages may be protected using a single leaf key

For any given SA the IV MUST NOT repeat, but there is no requirement that IV is unpredictable.

4.3. Nonce Format for MGM

MGM requires a per-message nonce (called Initial Counter Nonce, ICN, in the [RFC9058]) that must be unique in the context of any leaf key. The size of the ICN is $n-1$ bits, where n is the block size of the underlying cipher. The two ciphers used in the transforms defined in this document have different block sizes, so two different formats for the ICN are defined.

MGM specification requires that the nonce be $n-1$ bits in size, where n is the block size of the underlying cipher. This document defines MGM nonces having n bits (the block size of the underlying cipher) in size. Since the n is always a multiple of 8 bits, this makes MGM nonces having a whole number of octets. When used inside MGM the most significant bit of the first octet of the nonce (represented as an octet string) is dropped, making an effective size of the nonce equal to $n-1$ bits. Note, that the dropped bit is a part of zero field (see Figure 2 and Figure 3) which is always set to 0, so no information is lost when it is dropped.

4.3.1. MGM Nonce Format for "Kuznyechik" based Transforms

For transforms based on "Kuznyechik" cipher (ENCR_KUZNYECHIK_MGM_KTREE and ENCR_KUZNYECHIK_MGM_MAC_KTREE) the ICN consists of a zero octet, a 24-bit message counter and a 96-bit secret salt, that is fixed for SA and is not transmitted.

Figure 2: Nonce format for "Kuznyechik" based transforms

where:

- o zero (1 octet) - set to 0

Smyslov

Expires June 4, 2022

[Page 6]

- o pnum (3 octets) - the counter for the messages protected by the given leaf key; this field MUST be equal to the pnum field in the IV
- o salt (12 octets) - secret salt

4.3.2. MGM Nonce Format for "Magma" based Transforms

For transforms based on "Magma" cipher (ENCR_MAGMA_MGM_KTREE and ENCR_MAGMA_MGM_MAC_KTREE) the ICN consists of a zero octet, a 24-bit message counter and a 32-bit secret salt, that is fixed for SA and is not transmitted.

Figure 3: Nonce format for "Magma" based transforms

where:

- o zero (1 octet) - set to 0
- o pnum (3 octets) - the counter for the messages protected by the given leaf key; this field MUST be equal to the pnum field in the IV
- o salt (4 octets) - secret salt

4.4. Keying Material

The key for ENCR_KUZNYECHIK_MGM_KTREE and ENCR_KUZNYECHIK_MGM_MAC_KTREE transforms consists of 352 bits, of which the first 256 bits is a root key for the tree (denoted as K in [Section 4.1](#)) and the remaining 96 bits is a secret salt (see [Section 4.3.1](#)).

The key for ENCR_MAGMA_MGM_KTREE and ENCR_MAGMA_MGM_MAC_KTREE transforms consists of 288 bits, of which the first 256 bits is a root key for the tree (denoted as K in [Section 4.1](#)) and the remaining 32 bits is a secret salt (see [Section 4.3.2](#)).

The keys in case ESP are extracted from the KEYMAT, and in case IKEv2 they are SK_ei/SK_er keys. Note, that since these transforms provide

authenticated encryption, no additional keys are needed for authentication. It means that in case of IKEv2 the keys SK_ai/SK_ar are not used.

4.5. Integrity Check Value

The MGM computes authentication tag equal to the block size of the underlying cipher. For "Kuznyechik" based transforms (ENCR_KUZNYECHIK_MGM_KTREE and ENCR_KUZNYECHIK_MGM_MAC_KTREE) the resulting Integrity Check Value (ICV) is truncated to 96 bits by dropping the last 4 octets of the produced authentication tag. For "Magma" based transforms (ENCR_MAGMA_MGM_KTREE and ENCR_MAGMA_MGM_MAC_KTREE) the full 64-bit authentication tag is used as ICV.

4.6. Plaintext Padding

Transforms defined in this document don't require any plaintext padding, as specified in [[RFC9058](#)]. It means, that only those padding requirements that are imposed by the protocol are applied (4 bytes for ESP, no padding for IKEv2).

4.7. AAD Construction

4.7.1. ESP AAD

Additional Authenticated Data (AAD) in ESP is constructed differently depending on the transform being used and whether Extended Sequence Number (ESN) is in use or not. The ENCR_KUZNYECHIK_MGM_KTREE and ENCR_MAGMA_MGM_KTREE provide confidentiality, so the content of the ESP body is encrypted and AAD consists of the ESP SPI and (E)SN. The AAD is constructed similarly to the one in [[RFC4106](#)].

On the other hand the ENCR_KUZNYECHIK_MGM_MAC_KTREE and ENCR_MAGMA_MGM_MAC_KTREE don't provide confidentiality, they provide only message authentication. For this purpose the IV and the part of ESP packet that is normally encrypted are included in the AAD. For these transforms encryption capability provided by MGM is not used. The AAD is constructed similarly to the one in [[RFC4543](#)].

Figure 4: AAD for AEAD transforms with 32-bit SN

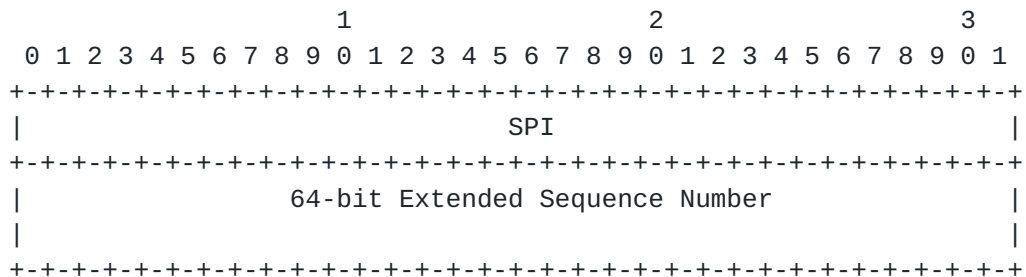

Figure 5: AAD for AEAD transforms with 64-bit ESN

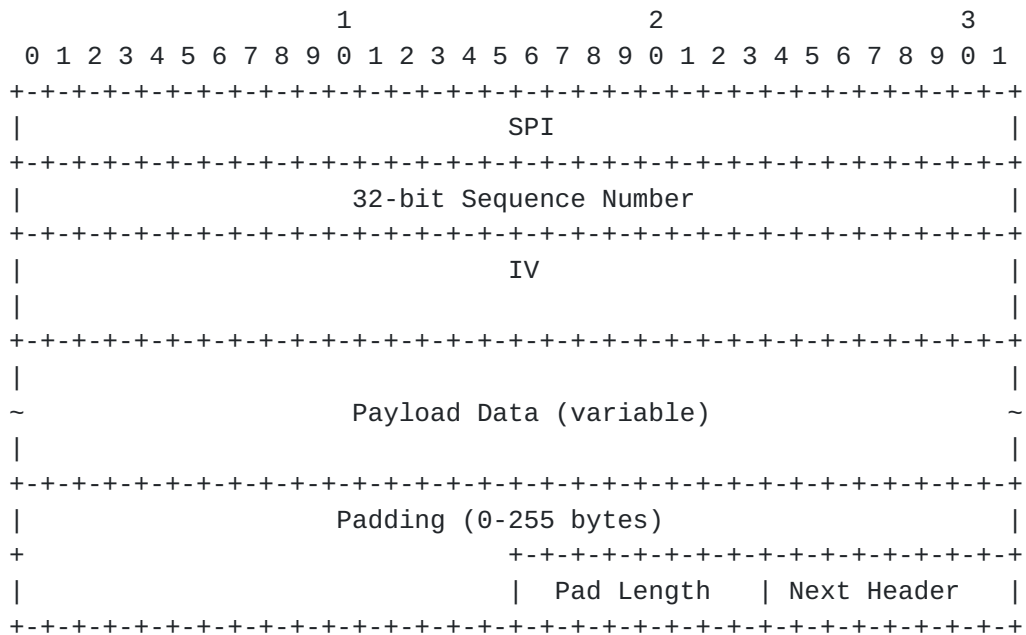

Figure 6: AAD for authentication only transforms with 32-bit SN

Figure 7: AAD for authentication only transforms with 64-bit ESN

4.7.2. IKEv2 AAD

For IKEv2 the AAD consists of the IKEv2 Header, any unencrypted payloads followed it (if they are present) and the Encrypted (or the Encrypted Fragment) payload header. The AAD is constructed similar to one in [RFC5282](#).

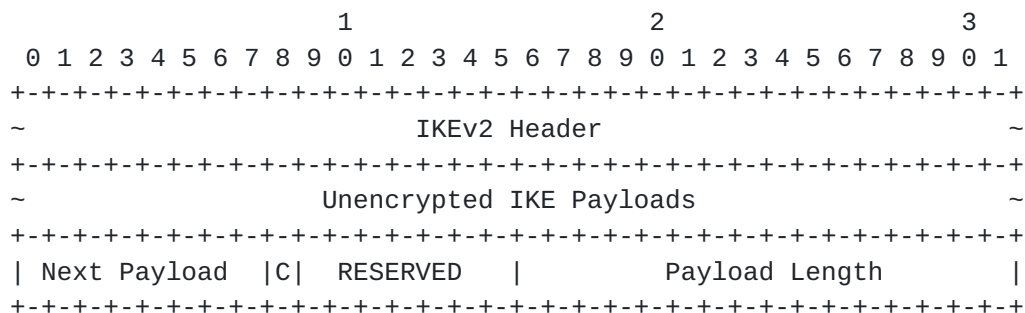

Figure 8: AAD for IKEv2

4.8. Using Transforms

When SA is established the i1, i2 and i3 parameters are set to 0 by the sender and a leaf key is calculated. The pnum parameter starts from 0 and is incremented with each message protected by the same leaf key. When sender decides that the leaf should be changed, it increments i3 parameter and generates a new leaf key. The pnum

parameter for the new leaf key is reset to 0 and the process continues. If the sender decides, that 3-rd level key corresponding to *i3* is used enough times, it increments *i2*, resets *i3* to 0 and calculates a new leaf key. The *pnum* is reset to 0 (as with every new leaf key) and the process continues. Similar procedure is used when 2-nd level key needs to be changed.

Note, that a combination of *i1*, *i2*, *i3* and *pnum* MUST NOT repeat for any particular SA. This means that wrapping around of these counters is not allowed: when *i2*, *i3* or *pnum* reach their maximum values, a procedure of changing a leaf key described above is executed, and when *i3* reaches its maximum value, the IPsec SA becomes unusable.

There may be other reasons to recalculate leaf keys beside reaching maximum values for the counters. For example, the sender may count a number of octets protected by a particular leaf key and generate a new key when some threshold is reached.

The receiver always uses *i1*, *i2* and *i3* from the received message. If they differ from the values in previously received packets, a new leaf key is calculated. The *pnum* parameter is always used from the received packet. To improve performance implementations may cache recently used leaf key. When new leaf key is calculated (based on the values from received message) the old key may be kept for some time to improve performance in case of possible packet reordering (when packets protected by the old leaf key are delayed and arrive later).

5. Security Considerations

The most important security consideration for MGM is that the nonce MUST NOT repeat for a given key. For this reason the transforms defined in this document MUST NOT be used with manual keying.

Security properties of MGM are discussed in [[MGM-SECURITY](#)].

6. IANA Considerations

IANA maintains a registry of "Internet Key Exchange Version 2 (IKEv2) Parameters" with a sub-registry of "Transform Type Values". IANA has assigned four Transform IDs in the "Transform Type 1 - Encryption Algorithm Transform IDs" registry and is requested to update their references to this document (where RFCXXXX is this document):
