The AES-CMAC-96 Algorithm and its use with IPsec
draft-songlee-aes-cmac-96-04.txt

Status of This Memo

By submitting this Internet-Draft, each author represents that any applicable patent or other IPR claims of which he or she is aware have been or will be disclosed, and any of which he or she becomes aware will be disclosed, in accordance with [Section 6 of BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF), its areas, and its working groups. Note that other groups may also distribute working documents as Internet-Drafts.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

The list of current Internet-Drafts can be accessed at <http://www.ietf.org/ietf/lid-abstracts.txt>.

Abstract

National Institute of Standards and Technology (NIST) has newly specified the Cipher based MAC (CMAC) which is equivalent to the One-Key CBC-MAC1 (OMAC1) algorithm submitted by Iwata and Kurosawa. OMAC1 efficiently reduces the key size of Extended Cipher Block Chaining mode (XCBC). This memo specifies the use of CMAC mode on authentication mechanism of IPsec Encapsulating Security Payload (ESP) and the Authentication Header (AH) protocols. This new algorithm is named AES-CMAC-96.

Internet Draft

February 2006

[1.](#) Introduction

National Institute of Standards and Technology (NIST) has newly specified the Cipher-based Message Authentication Code (CMAC). CMAC [NIST-CMAC] is a message authentication code that is based on a symmetric key block cipher such as the Advanced Encryption Standard [[NIST-AES](#)]. CMAC is equivalent to the One-Key CBC MAC1 (OMAC1) submitted by Iwata and Kurosawa [[OMAC1a](#), [OMAC1b](#)]. OMAC1 is an improvement of the eXtended Cipher Block Chaining mode (XCBC) submitted by Black and Rogaway [[XCBCa](#), [XCBCb](#)], which itself is an improvement of the basic CBC-MAC. XCBC efficiently addresses the security deficiencies of CBC-MAC, and OMAC1 efficiently reduces the key size of XCBC.

This memo specifies the usage of CMAC on authentication mechanism of IPsec Encapsulating Security Payload (ESP) [[ESP](#)] and the Authentication Header (AH) protocols. This new algorithm is named AES-CMAC-96. For further information on AH and ESP, refer to [[AH](#)] and [[ROADMAP](#)].

[2.](#) Basic definitions

CBC	Cipher Block Chaining mode of operation for message authentication code.
MAC	Message Authentication Code. A bit string of a fixed length, computed by MAC generation algorithm, that is used to establish the authority and hence, the integrity of a message.
CMAC	Cipher-based MAC based on an approved symmetric key block cipher, such as the Advanced Encryption Standard.
Key (K)	128-bits (16 octets) long key for AES-128 cipher block. Denoted by K.
Message (M)	Message to be authenticated. Denoted by M.

Length (len)	The length of message M in octets. Denoted by len. Minimum value of the length can be 0. The maximum value of the length is not specified in this document.
truncate(T,l)	Truncate T (MAC) in msb-first order with l octet.
T	The output of AES-CMAC

Truncated T	The truncated output of AES-CMAC-128 in MSB first order.
AES-CMAC	CMAC generation function based on AES block cipher with 128-bits key
AES-CMAC-96	IPsec AH and ESP MAC generation function based on AES-CMAC which truncates MSB 96 bits of 128 bits output

[3.](#) AES-CMAC

The core of AES-CMAC-96 is the AES-CMAC [[AES-CMAC](#)]. The underlying algorithm for AES-CMAC are Advanced Encryption Standard cipher block [AES] and recently defined CMAC mode of operation [NIST-CMAC]. AES-CMAC provides stronger assurance of data integrity than a checksum or an error detecting code. The verification of a checksum or an error detecting code detects only accidental modifications of the data, while CMAC is designed to detect intentional, unauthorized modifications of the data, as well as accidental modifications. The output of AES-CMAC can validate the input message. Validating the message provide assurance of the integrity and authenticity over the message from the source. According to [NIST-CMAC] at least 64-bits should be used for against guessing attack. AES-CMAC achieves the similar security goal of HMAC [[RFC-HMAC](#)]. Since AES-CMAC is based on a symmetric key block cipher, AES, while HMAC is based on a hash function, such as SHA-1, AES-CMAC is appropriate for information systems in which AES is more readily available than a hash function. For detail information about AES-CMAC is available in [[AES-CMAC](#)] and [NIST-CMAC].

[4.](#) AES-CMAC-96

For use in IPsec message authentication on AH and ESP, AES-CMAC-96 should be used. AES-CMAC-96 is a AES-CMAC with 96-bit-long truncated output in most significant bit first order. The output of 96 bits MAC that will meet the default authenticator length as specified in [AH]. The result of truncation is taken in most significant bits first order. For further information on AES-CMAC, refer to [AES-CMAC] and [NIST-CMAC].

Figure 1 describes AES-CMAC-96 algorithm:

In step 1, AES-CMAC is applied to the message 'M' in length 'len' with key 'K'

In step 2, Truncate output block, T with 12 octets in msb-first-order and return TT.

[6.](#) Interaction with the ESP Cipher Mechanism

As of this writing, there are no known issues which preclude the use of AES-CMAC-96 with any specific cipher algorithm.

[7.](#) Security Considerations

See security consideration of [\[AES-CMAC\]](#).

[8.](#) IANA Consideration

IANA should allocate a value for IKEv2 Transform Type 3 (Integrity Algorithm) to the AUTH_AES_CMAC_96 algorithm when this document is published.

[9.](#) Acknowledgement

Portions of this text were borrowed from [\[NIST-CMAC\]](#) and [\[AES-XCBC-MAC\]](#). We would like to thank to Russ Housley for his

useful comments.
