Interaction between SIP and HIP
draft-tschofenig-hiprg-host-identities-06.txt

Status of this Memo

Abstract

This document investigates the interworking between the Session Initiation Protocol (SIP) and the Host Identity Protocol (HIP) and the benefits that may arise from their combined operation.
The aspect of exchanging Host Identities (or Host Identity Tags) in SIP/SDP for later usage with the Host Identity Protocol Protocol (HIP) is described in more detail as an example of this interworking.

Table of Contents

---

1. Introduction

TOC

SIP [1] (Rosenberg, J., Schulzrinne, H., Camarillo, G., Johnston, A., Peterson, J., Sparks, R., Handley, M., and E. Schooler, “SIP: Session Initiation Protocol,” June 2002.) enables a pair of user agents to establish and maintain sessions. The communication typically involves SIP proxies before prior to communication between the end points taking place. As part of the initial exchange, a number of parameters are exchanged. Certain of these parameters are relevant to security. Examples of such parameters are keying material and other cryptographic information that is used in order to establish a security association for the protection of subsequent data traffic.
HIP (see [2] (Moskowitz, R. and P. Nikander, “Host Identity Protocol Architecture,” August 2005.) and [3] (Moskowitz, R., Nikander, P., Jokela, P., and T. Henderson, “Host Identity Protocol,” October 2007.)) propose an architecture with a cryptographic namespace and a layer between the network and the transport layer. This layer is used in order to shield applications from the impact of multi-homing, readdressing and mobility. A protocol, called the Host Identity Protocol, is used in order to establish state at the two end hosts. This state includes the establishment of IPsec SAs.

TOC

2. Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119 (Bradner, S., "Key words for use in RFCs to Indicate Requirement Levels," March 1997.) [4].

---

3. Exchanging Host Identities with SIP

TOC

3.1. Concept

TOC

In order to provide security between two HIP end hosts beyond opportunistic encryption it is necessary to securely retrieve the Host Identities. A number of mechanisms can be used including directories (such as DNS) or more advanced concepts for example based on Distributed Hash Tables typically used in peer-to-peer networks. This document suggests to exchange the Host Identities (or Host Identity Tags) as part of the initial SIP exchange inside the SDP payload. As such, the Host Identities can also be bound to the user identities - a concept not used in HIP.
Figure 1 (SIP Trapezoid) illustrates the main idea:

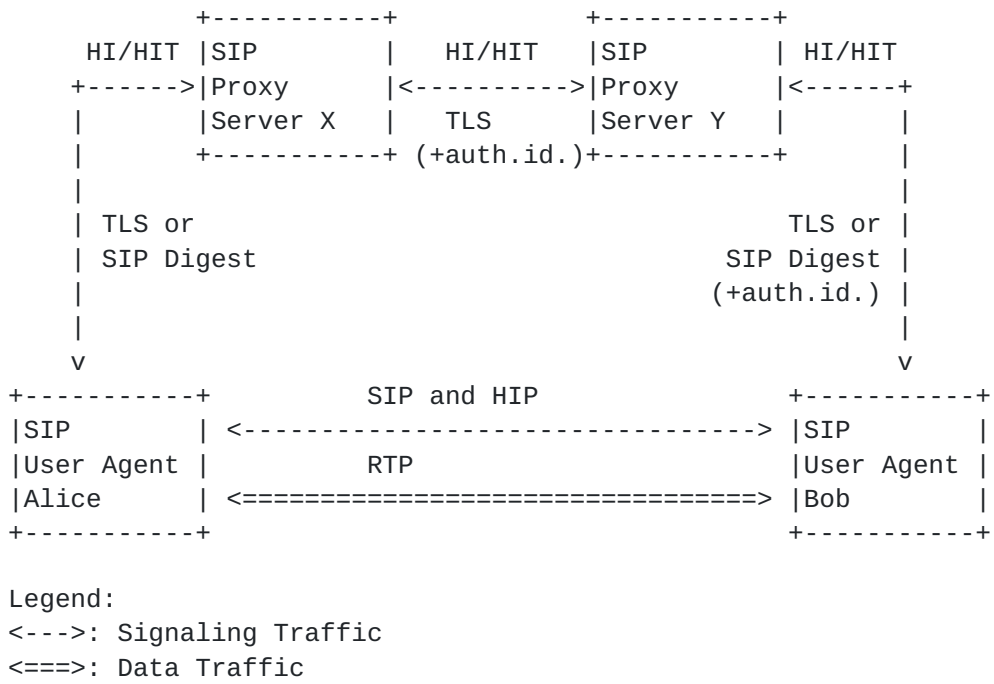

Figure 1: SIP Trapezoid

The initial SIP signaling messages between Alice and Bob often take place via the proxy servers. This exchange may be protected with TLS (between SIP proxies but also between SIP UAs and SIP proxies) or with SIP digest authentication between SIP UAs and the outbound proxy. Further SIP security mechanisms should be used in combination with this proposal. The security consideration section, see Section 4 (Security Considerations), provides a discussion about the possible approaches to secure the Host Identity Tag and to relate it ongoing session.
This allows two hosts to securely exchange keys even if there are only domain-level public and private keys, as well as secure associations within a domain, thus avoiding the need for a global user-level PKI.
This initial message exchange is used to exchange Host Identities between the end points within the SDP payload.
Subsequently, when both user agents Alice and Bob communicate directly with each other they are able to reuse the Host Identity for the HIP message exchange.
If the SIP communication does not involve third parties (i.e., SIP proxies) and is therefore executed directly between the two SIP UAs then it is not useful to exchange Host Identities in the SDP payloads since the HIP exchange already took place before the first SIP message can be exchanged between the two peers. Still HIP might provide some advantages for the end-to-end communication, such as providing security at the lower layer and mobility and multi-homing support.
The security of this approach relies on two properties:

> The signaling messages and the data traffic traverse a different path. Hence, an adversary needs to be located where it is able to see both, the signaling and the the data traffic.
>
> The signaling traffic is often protected.

3.2. SDP Extension

TOC

This document proposes to enhance the SDP [5] (Andreasen, F., “Session Description Protocol Security Descriptions for Media Streams,” September 2005.) 'k' or 'a' parameter.
The 'k' parameter has the following structure:
k=<method>:<encryption key>
This document defines two new method fields:

> k=host-identity:<HIP Host Identity>
>
> k=host-identity-tag:<hash of the public key>

Alternatively, the 'a' parameter could be used like [6] (Arkko, J., “Key Management Extensions for Session Description Protocol (SDP) and

Real Time Streaming Protocol (RTSP)," June 2005.) proposes. An example for MIKEY [9] (Arkko, J., Carrara, E., Lindholm, F., Naslund, M., and K. Norrman, "MIKEY: Multimedia Internet KEYing," August 2004.) is given in the reference, which could be reused for HIP. As defined in [10] (Handley, M., "SDP: Session Description Protocol," January 2006.), the 'a' parameter has the following structure:
a=<attribute>:<value>
Similar to the MIKEY example in [6] (Arkko, J., "Key Management Extensions for Session Description Protocol (SDP) and Real Time Streaming Protocol (RTSP)," June 2005.), this document defines two new method fields:

> a=key-mgmt:host-identity <HIP Host Identity>
>
> a=key-mgmt:host-identity-tag <hash of the public key>

Both, the Host Identity and the Host Identity Tag are defined in [3] (Moskowitz, R., Nikander, P., Jokela, P., and T. Henderson, "Host Identity Protocol," October 2007.). The Host Identity contains the public key and a number of cryptographic parameters (such as used algorithms and Diffie-Hellmann public parameters). The Host Identity is base64 encoded.
FOR DISCUSSION:

> The usage of the k parameter as defined in [7] (Handley, M. and V. Jacobson, "SDP: Session Description Protocol," April 1998.) is deprecated. [5] (Andreasen, F., "Session Description Protocol Security Descriptions for Media Streams," September 2005.) is more appropriate but like 'k=', they come with the caveat that they require a secured e2e signaling path (or SDP is S/MIME protected). One alternative is the usage of MIKEY for the exchange as defined in [6] (Arkko, J., "Key Management Extensions for Session Description Protocol (SDP) and Real Time Streaming Protocol (RTSP)," June 2005.).
>
> Furthermore, and probably more important, it is important to said what the Host Identity is supposed to be used with. They may help avoiding re-INVITEs when underlying IP addresses change to update the 'Contact:' address as well as the addresses in the 'c=' lines for the various media.
>
> However, multiple devices may take part in the different media sessions (your laptop doing video in parallel to your hardware IP phone). To support these cases, it may be necessary to exchange _several_ HI(T)s within SDP and denote what they shall be used for. Such a mapping could naturally be achieved for each media stream (even using 'k=' attributes); at simple 'a=' attributes (or the mechanisms from [5] (Andreasen, F., "Session Description Protocol Security Descriptions for Media Streams," September 2005.)/ [6] (Arkko, J., "Key Management Extensions for Session Description

> Protocol (SDP) and Real Time Streaming Protocol (RTSP),” June 2005.) would be preferred.
>
> SDP only deals with media streams and does not have a notion of user or main device in the background. Hence, the SIP HI(T) may need to go into SIP signaling (rather than be carried in SDP).
>
> Logically, this appears to belong to the 'Contact:' header which may be conveyed protected in an S/MIME body (signed and encrypted).

3.3. Example

TOC

This example contains the full details of the example session setup taken from Section 4 of [1] (Rosenberg, J., Schulzrinne, H., Camarillo, G., Johnston, A., Peterson, J., Sparks, R., Handley, M., and E. Schooler, “SIP: Session Initiation Protocol,” June 2002.). The message flow is shown in Figure 1 of [1] (Rosenberg, J., Schulzrinne, H., Camarillo, G., Johnston, A., Peterson, J., Sparks, R., Handley, M., and E. Schooler, “SIP: Session Initiation Protocol,” June 2002.) and resembles the architecture shown in Figure 1 (SIP Trapezoid). Note that these flows show the minimum required set of header fields; some other header fields such as Allow and Supported would normally be present. In our example Alice uses the following Host Identity Tag (7214148E0433AFE2FA2D48003D31172E) and Bob uses (44A5C522D7EDEDF962E55A0677DB1346) as the HIT. These HITs correspond to the following Host Identities (for convenience we reuse the XML representation format used by the Boeing implementation).

```

The media session between Alice and Bob is now established.
The exchanged HITs are now placed in the pool of known HITs at both end hosts. As such there is also a binding established between URI and HIT at this point.
Next a regular HIP base exchange between Alice and Bob is started. As part of the exchange the two end hosts inspect their known-HITs pool and find the previously exchanged parameters.

```
Alice -> Bob: I1: Trigger exchange

Alice <- Bob: R1: {Puzzle, D-H(R), HI(R), ESP Transform,
              HIP Transform }SIG

Alice -> Bob: I2: {Solution, LSI(I), SPI(I), D-H(I),
              ESP Transform, HIP Transform, {H(I)}SK }SIG

Alice <- Bob: R2: {LSI(R), SPI(R), HMAC}SIG
```

As a result of this exchange, two IPsec SAs (one for each direction) is established. RTP media traffic can be exchanged between the two end hosts, Alice and Bob, protected by IPsec. If end host mobility takes place then a HIP readdressing exchange takes place which is not detected at the upper layer by UDP/RTP or SIP.

---

4. Security Considerations

TOC

The standard HIP strategy for authenticating the communicating parties is to give the Initiator and the Responder a Host Identity and to assure the authenticity of the Host Identity via external mechanisms, such as DNSSEC (if the Host Identities are stored in the DNS). The Initiator then verifies the Host Identity and checks its validity. The complexity of ensuring that the Host Identity has not been tampered with is pushed to DNS (and DNSSEC), as the only mechanism specified for ensuring that the public key is genuine. The infrastructure provided for SIP can provide a similar, but more deployment friendly, functionality when combined with already available SIP security mechanisms.
The design described in this document is intended to leverage the authenticity of the signaling channel (while not requiring

confidentiality). As long as each side of the connection can verify the integrity of the SDP INVITE then the HIP base exchange handshake cannot be hijacked via a man-in-the-middle attack. This integrity protection is easily provided by the caller to the callee via the SIP Identity [11] (Peterson, J. and C. Jennings, "Enhancements for Authenticated Identity Management in the Session Initiation Protocol (SIP)," August 2006.) mechanism. However, it is less straightforward for the responder.

Ideally Alice would want to know that Bob's SDP had not been tampered with and who it was from so that Alice's User Agent could indicate to Alice that there was a secure phone call to Bob. This is known as the SIP Response Identity problem and is still a topic of ongoing work in the SIP community. When a solution to the SIP Response Identity problem is finalized, it SHOULD be used here. In the meantime there are several approaches that can be used to mitigate this problem: Use UPDATE, Use SIPS, Use S/MIME, and do nothing. Each one is discussed here followed by the security implications of that approach.

4.1. UPDATE

TOC

In this approach, Bob sends an answer, then immediately follows up with an UPDATE that includes the Host Identity Tag and uses the SIP Identity mechanism to assert that the message is from Bob's. The downside of this approach is that it requires the extra round trip of the UPDATE. However, it is simple and secure even when the proxies are not trusted.

4.2. SIPS

TOC

In this approach, the signaling is protected by TLS from hop to hop. As long as all proxies are trusted, this provides integrity for the Host Identity Tag. It does not provide a strong assertion of who Alice is communicating with. However, as much as the target domain can be trusted to correctly populate the From header field value, Alice can use that. The security issue with this approach is that if one of the Proxies wished to mount a man-in-the-middle attack, it could convince Alice that she was talking to Bob when really the media was flowing through a man in the middle media relay. However, this attack could not convince Bob that he was taking to Alice.

4.3. S/MIME

TOC

RFC 3261 (Rosenberg, J., Schulzrinne, H., Camarillo, G., Johnston, A., Peterson, J., Sparks, R., Handley, M., and E. Schooler, "SIP: Session Initiation Protocol," June 2002.) [1] defines a S/MIME security mechanism for SIP that could be used to sign that the fingerprint was

from Bob. This would be secure. However, so far there have been no deployments of S/MIME for SIP.

4.4. Single-sided Verification

TOC

In this approach, no integrity is provided for the fingerprint from Bob to Alice. In this approach, an attacker that was on the signaling path could tamper with the fingerprint and insert themselves as a man-in-the-middle on the media. Alice would know that she had a secure call with someone but would not know if it was with Bob or a man-in-the-middle. Bob would know that an attack was happening. The fact that one side can detect this attack means that in most cases where Alice and Bob both wish the communications to be encrypted there is not a problem. Keep in mind that in any of the possible approaches Bob could always reveal the media that was received to anyone. We are making the assumption that Bob also wants secure communications. In this do nothing case, Bob knows the media has not been tampered with or intercepted by a third party and that it is from Alice. Alice knows that she is talking to someone and that whoever that is has probably checked that the media is not being intercepted or tampered with. This approach is certainly less than ideal but very usable for many situations. An alternative available to Alice and Bob is to use human speech to verified each others' identity then verify each others' Host Identity Tags also using human speech. Assuming that it is difficult to impersonate another's speech and seamlessly modify the audio contents of a call, this approach is relatively safe. On the other hand, SIP is not only used for voice communication.
Note that this proposal is closely aligned towards the usage of the 'k' parameter in SDP [7] (Handley, M. and V. Jacobson, “SDP: Session Description Protocol,” April 1998.). As a difference, an asymmetric key is exchanged unlike the proposals illustrated in Section 6 of [7] (Handley, M. and V. Jacobson, “SDP: Session Description Protocol,” April 1998.). Section 5.12 of [10] (Handley, M., “SDP: Session Description Protocol,” January 2006.) is relevant for this discussion. Please note that this approach is in a certain sense a re-instantiation of the Purpose-Built-Key (PBK) idea (see [12] (Bradner, S., Mankin, A., and J. Schiller, “A Framework for Purpose-Built Keys (PBK),” June 2003.)). With PBK a hash of a public key is sent from node A to node B. If there was no adversary between A and B at that time to modify the transmitted hash value then subsequent communication interactions which use the public key are secure. This proposal reuses the same idea but focuses on the interworking between different protocols. In fact it would be possible to use the same approach to exchange the hash of an S/MIME certificate which can later be used in subsequent SIP signaling message exchanges.
