JavaScript Session Establishment Protocol (JSEP)

Abstract

This document describes the mechanisms for allowing a JavaScript application to control the signaling plane of a multimedia session via the interface specified in the W3C RTCPeerConnection API and discusses how this relates to existing signaling protocols.

This specification obsoletes RFC 8829.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <https://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on 24 March 2024.

1. Introduction

This document describes how the W3C Web Real-Time Communication (WebRTC) `RTCPeerConnection` interface [[W3C.webrtc](#)] is used to control the setup, management, and teardown of a multimedia session.

1.1. General Design of JSEP

WebRTC call setup has been designed to focus on controlling the media plane, leaving signaling-plane behavior up to the application as much as possible. The rationale is that different applications may prefer to use different protocols, such as the existing SIP call signaling protocol, or something custom to the particular application, perhaps for a novel use case. In this approach, the key information that needs to be exchanged is the multimedia session description, which specifies the transport and media configuration information necessary to establish the media plane.

With these considerations in mind, this document describes the JavaScript Session Establishment Protocol (JSEP), which allows for full control of the signaling state machine from JavaScript. As described above, JSEP assumes a model in which a JavaScript application executes inside a runtime containing WebRTC APIs (the "JSEP implementation"). The JSEP implementation is almost entirely divorced from the core signaling flow, which is instead handled by the JavaScript making use of two interfaces: (1) passing in local and remote session descriptions and (2) interacting with the Interactive Connectivity Establishment (ICE) state machine [[RFC8445](#)]. The combination of the JSEP implementation and the JavaScript application is referred to throughout this document as a "JSEP endpoint".

In this document, the use of JSEP is described as if it always occurs between two JSEP endpoints. Note, though, that in many cases it will actually be between a JSEP endpoint and some kind of server, such as a gateway or Multipoint Control Unit (MCU). This distinction is invisible to the JSEP endpoint; it just follows the instructions it is given via the API.

JSEP's handling of session descriptions is simple and straightforward. Whenever an offer/answer exchange is needed, the initiating side creates an offer by calling a `createOffer` API. The application then uses that offer to set up its local configuration via the `setLocalDescription` API. The offer is finally sent off to the remote side over its preferred signaling mechanism (e.g.,

WebSockets); upon receipt of that offer, the remote party installs it using the `setRemoteDescription` API.

To complete the offer/answer exchange, the remote party uses the `createAnswer` API to generate an appropriate answer, applies it using the `setLocalDescription` API, and sends the answer back to the initiator over the signaling channel. When the initiator gets that answer, it installs it using the `setRemoteDescription` API, and initial setup is complete. This process can be repeated for additional offer/answer exchanges.

Regarding ICE [[RFC8445](#)], JSEP decouples the ICE state machine from the overall signaling state machine. The ICE state machine must remain in the JSEP implementation because only the implementation has the necessary knowledge of candidates and other transport information. Performing this separation provides additional flexibility in protocols that decouple session descriptions from transport. For instance, in traditional SIP, each offer or answer is self-contained, including both the session descriptions and the transport information. However, [[RFC8840](#)] allows SIP to be used with Trickle ICE [[RFC8838](#)], in which the session description can be sent immediately and the transport information can be sent when available. Sending transport information separately can allow for faster ICE and DTLS startup, since ICE checks can start as soon as any transport information is available rather than waiting for all of it. JSEP's decoupling of the ICE and signaling state machines allows it to accommodate either model.

Although it abstracts signaling, the JSEP approach requires that the application be aware of the signaling process. While the application does not need to understand the contents of session descriptions to set up a call, the application must call the right APIs at the right times, convert the session descriptions and ICE information into the defined messages of its chosen signaling protocol, and perform the reverse conversion on the messages it receives from the other side.

One way to make life easier for the application is to provide a JavaScript library that hides this complexity from the developer; said library would implement a given signaling protocol along with its state machine and serialization code, presenting a higher-level call-oriented interface to the application developer. For example, libraries exist to provide implementations of the SIP [[RFC3261](#)] and Extensible Messaging and Presence Protocol (XMPP) [[RFC6120](#)] signaling protocols atop the JSEP API. Thus, JSEP provides greater control for the experienced developer without forcing any additional complexity on the novice developer.

1.2. Other Approaches Considered

One approach that was considered instead of JSEP was to include a lightweight signaling protocol. Instead of providing session descriptions to the API, the API would produce and consume messages from this protocol. While providing a more high-level API, this put more control of signaling within the JSEP implementation, forcing it to have to understand and handle concepts like signaling glare (see [[RFC3264](#)], [Section 4](#)).

A second approach that was considered but not chosen was to decouple the management of the media control objects from session descriptions, instead offering APIs that would control each component directly. This was rejected based on the argument that requiring exposure of this level of complexity to the application programmer would not be beneficial; it would (1) result in an API where even a simple example would require a significant amount of code to orchestrate all the needed interactions and (2) create a large API surface that would need to be agreed upon and documented. In addition, these API points could be called in any order, resulting in a more complex set of interactions with the media subsystem than the JSEP approach, which specifies how session descriptions are to be evaluated and applied.

One variation on JSEP that was considered was to keep the basic session-description-oriented API but to move the mechanism for generating offers and answers out of the JSEP implementation. Instead of providing `createOffer/createAnswer` methods within the implementation, this approach would instead expose a `getCapabilities` API, which would provide the application with the information it needed in order to generate its own session descriptions. This increases the amount of work that the application needs to do; it needs to know how to generate session descriptions from capabilities, and especially how to generate the correct answer from an arbitrary offer and the supported capabilities. While this could certainly be addressed by using a library like the one mentioned above, it basically forces the use of said library even for a simple example. Providing `createOffer/createAnswer` avoids this problem.

1.3. Changes from RFC 8829

When [[RFC8829](#)] was published, inconsistencies regarding BUNDLE [[RFC8843](#)] operation were identified with regard to both the specification text as well as implementation behavior. The former concern was addressed via an update to BUNDLE (see [[RFC9143](#)]). For the latter concern, it was observed that some implementations implemented the "max-bundle" bundle policy defined in [[RFC8829](#)] by assuming that bundling had already been negotiated, rather than marking "m=" sections as bundle-only as indicated by the BUNDLE

specification. In order to prevent unexpected changes to applications relying on the pre-standard behavior, the decision was made to deprecate "max-bundle" and instead introduce an identically defined "must-bundle" policy that, when selected, provides the behavior originally specified by [\[RFC8829\]](#).

2. Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [\[RFC2119\]](#) [\[RFC8174\]](#) when, and only when, they appear in all capitals, as shown here.

3. Semantics and Syntax

3.1. Signaling Model

JSEP does not specify a particular signaling model or state machine, other than the generic need to exchange session descriptions in the fashion described by [\[RFC3264\]](#) (offer/answer) in order for both sides of the session to know how to conduct the session. JSEP provides mechanisms to create offers and answers, as well as to apply them to a session. However, the JSEP implementation is totally decoupled from the actual mechanism by which these offers and answers are communicated to the remote side, including addressing, retransmission, forking, and glare handling. These issues are left entirely up to the application; the application has complete control over which offers and answers get handed to the implementation, and when.

Figure 1: JSEP Signaling Model

3.2. Session Descriptions and State Machine

In order to establish the media plane, the JSEP implementation needs specific parameters to indicate what to transmit to the remote side, as well as how to handle the media that is received. These parameters

are determined by the exchange of session descriptions in offers and answers, and there are certain details to this process that must be handled in the JSEP APIs.

Whether a session description applies to the local side or the remote side affects the meaning of that description. For example, the list of codecs sent to a remote party indicates what the local side is willing to receive, which, when intersected with the set of codecs the remote side supports, specifies what the remote side should send. However, not all parameters follow this rule; some parameters are declarative, and the remote side must either accept them or reject them altogether. An example of such a parameter is the TLS fingerprints [[RFC8122](#)] as used in the context of DTLS [[RFC6347](#)]; these fingerprints are calculated based on the local certificate(s) offered and are not subject to negotiation.

In addition, various RFCs put different conditions on the format of offers versus answers. For example, an offer may propose an arbitrary number of "m=" sections (i.e., media descriptions as described in [[RFC4566](#)], [Section 5.14](#)), but an answer must contain the exact same number as the offer.

Lastly, while the exact media parameters are known only after an offer and an answer have been exchanged, the offerer may receive ICE checks, and possibly media (e.g., in the case of a re-offer after a connection has been established) before it receives an answer. To properly process incoming media in this case, the offerer's media handler must be aware of the details of the offer before the answer arrives.

Therefore, in order to handle session descriptions properly, the JSEP implementation needs:

1. To know if a session description pertains to the local or remote side.
2. To know if a session description is an offer or an answer.
3. To allow the offer to be specified independently of the answer.

JSEP addresses this by adding both `setLocalDescription` and `setRemoteDescription` methods and having session description objects contain a type field indicating the type of session description being supplied. This satisfies the requirements listed above for both the offerer, who first calls `setLocalDescription(sdp [offer])` and then later `setRemoteDescription(sdp [answer])`, and the answerer, who first calls `setRemoteDescription(sdp [offer])` and then later `setLocalDescription(sdp [answer])`.

During the offer/answer exchange, the outstanding offer is considered to be "pending" at the offerer and the answerer, as it may be either accepted or rejected. If this is a re-offer, each side will also have "current" local and remote descriptions, which reflect the result of the last offer/answer exchange. Sections [4.1.14](#), [4.1.16](#), [4.1.13](#), and [4.1.15](#) provide more detail on pending and current descriptions.

JSEP also allows for an answer to be treated as provisional by the application. Provisional answers provide a way for an answerer to communicate initial session parameters back to the offerer, in order to allow the session to begin, while allowing a final answer to be specified later. This concept of a final answer is important to the offer/answer model; when such an answer is received, any extra resources allocated by the caller can be released, now that the exact session configuration is known. These "resources" can include things like extra ICE components, Traversal Using Relays around NAT (TURN) candidates, or video decoders. Provisional answers, on the other hand, do no such deallocation; as a result, multiple dissimilar provisional answers, with their own codec choices, transport parameters, etc., can be received and applied during call setup. Note that the final answer itself may be different than any received provisional answers.

In [[RFC3264](#)], the constraint at the signaling level is that only one offer can be outstanding for a given session, but at the JSEP level, a new offer can be generated at any point. For example, when using SIP for signaling, if one offer is sent and is then canceled using a SIP CANCEL, another offer can be generated even though no answer was received for the first offer. To support this, the JSEP media layer can provide an offer via the createOffer method whenever the JavaScript application needs one for the signaling. The answerer can send back zero or more provisional answers and then finally end the offer/answer exchange by sending a final answer. The state machine for this is as follows:

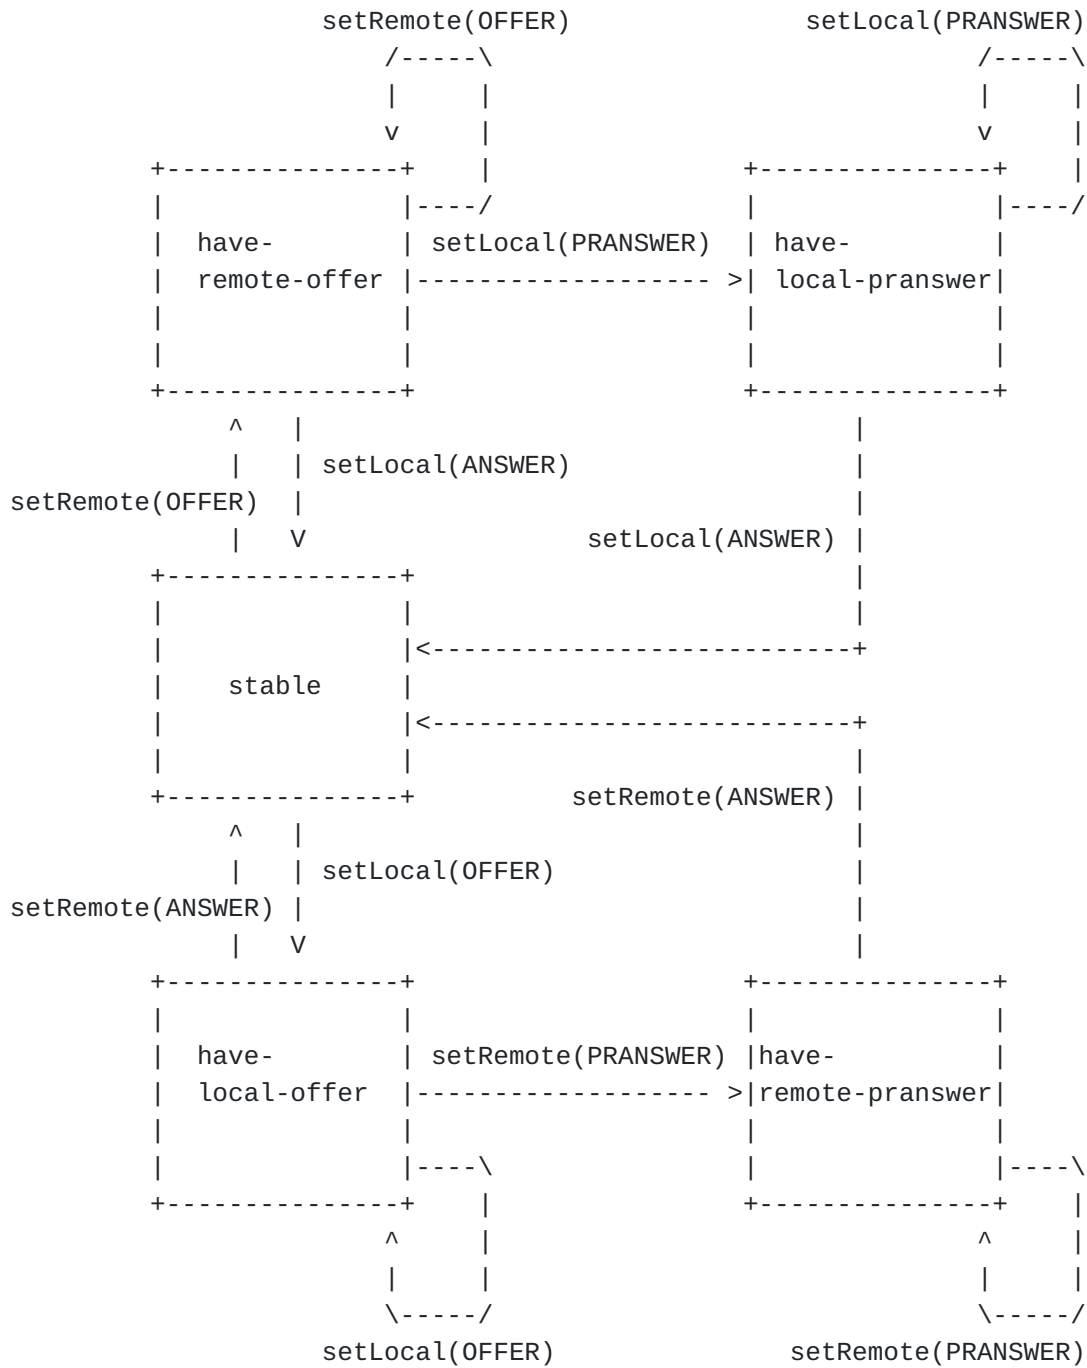

Figure 2: JSEP State Machine

Aside from these state transitions, there is no other difference between the handling of provisional ("pranswer") and final ("answer") answers.

3.3. Session Description Format

JSEP's session descriptions use Session Description Protocol (SDP) syntax for their internal representation. While this format is not optimal for manipulation from JavaScript, it is widely accepted and

is frequently updated with new features; any alternate encoding of session descriptions would have to keep pace with the changes to SDP, at least until the time that this new encoding eclipsed SDP in popularity.

However, to provide for future flexibility, the SDP syntax is encapsulated within a SessionDescription object, which can be constructed from SDP and be serialized out to SDP. If future specifications agree on a JSON format for session descriptions, this object could be enhanced to generate and consume that JSON.

As detailed below, most applications should be able to treat the SessionDescriptions produced and consumed by these various API calls as opaque blobs; that is, the application will not need to parse or understand them.

3.4. Session Description Control

In order to give the application control over various common session parameters, JSEP provides control surfaces that tell the JSEP implementation how to generate session descriptions. In most cases, this removes the need for applications to modify session descriptions after they are created.

Changes to these objects result in changes to the session descriptions generated by subsequent createOffer/createAnswer calls.

3.4.1. RtpTransceivers

RtpTransceivers allow the application to control the RTP media associated with one "m=" section. Each RtpTransceiver has an RtpSender and an RtpReceiver, which an application can use to control the sending and receiving of RTP media. The application may also modify the RtpTransceiver directly, for instance, by stopping it.

RtpTransceivers generally have a 1:1 mapping with "m=" sections, although there may be more RtpTransceivers than "m=" sections when RtpTransceivers are created but not yet associated with an "m=" section, or if RtpTransceivers have been stopped and disassociated from "m=" sections. An RtpTransceiver is said to be associated with an "m=" section if its media identification (mid) property is non-null; otherwise, it is said to be disassociated. The associated "m=" section is determined using a mapping between transceivers and "m=" section indices, formed when creating an offer or applying a remote offer.

An RtpTransceiver is never associated with more than one "m=" section, and once a session description is applied, an "m=" section is always associated with exactly one RtpTransceiver. However, in certain cases where an "m=" section has been rejected, as discussed

in [Section 5.2.2](#) below, that "m=" section will be "recycled" and associated with a new RtpTransceiver with a new MID value.

RtpTransceivers can be created explicitly by the application or implicitly by calling setRemoteDescription with an offer that adds new "m=" sections.

3.4.2. RtpSenders

RtpSenders allow the application to control how RTP media is sent. An RtpSender is conceptually responsible for the outgoing RTP stream(s) described by an "m=" section. This includes encoding the attached MediaStreamTrack, sending RTP media packets, and generating/processing the RTP Control Protocol (RTCP) for the outgoing RTP streams(s).

3.4.3. RtpReceivers

RtpReceivers allow the application to inspect how RTP media is received. An RtpReceiver is conceptually responsible for the incoming RTP stream(s) described by an "m=" section. This includes processing received RTP media packets, decoding the incoming stream(s) to produce a remote MediaStreamTrack, and generating/processing RTCP for the incoming RTP stream(s).

3.5. ICE

3.5.1. ICE Gathering Overview

JSEP gathers ICE candidates as needed by the application. Collection of ICE candidates is referred to as a gathering phase, and this is triggered either by the addition of a new or recycled "m=" section to the local session description or by new ICE credentials in the description, indicating an ICE restart. Use of new ICE credentials can be triggered explicitly by the application or implicitly by the JSEP implementation in response to changes in the ICE configuration.

When the ICE configuration changes in a way that requires a new gathering phase, a 'needs-ice-restart' bit is set. When this bit is set, calls to the createOffer API will generate new ICE credentials. This bit is cleared by a call to the setLocalDescription API with new ICE credentials from either an offer or an answer, i.e., from either a locally or remotely initiated ICE restart.

When a new gathering phase starts, the ICE agent will notify the application that gathering is occurring through a state change event. Then, when each new ICE candidate becomes available, the ICE agent will supply it to the application via an onicecandidate event; these candidates will also automatically be added to the current and/or pending local session description. Finally, when all candidates have

been gathered, a final onicecandidate event will be dispatched to signal that the gathering process is complete.

Note that gathering phases only gather the candidates needed by new/recycled/restarting "m=" sections; other "m=" sections continue to use their existing candidates. Also, if an "m=" section is bundled (either by a successful bundle negotiation or by being marked as bundle-only), then candidates will be gathered and exchanged for that "m=" section if and only if its MID item is a BUNDLE-tag, as described in [[RFC9143](#)].

3.5.2. ICE Candidate Trickling

Candidate trickling is a technique through which a caller may incrementally provide candidates to the callee after the initial offer has been dispatched; the semantics of "Trickle ICE" are defined in [[RFC8838](#)]. This process allows the callee to begin acting upon the call and setting up the ICE (and perhaps DTLS) connections immediately, without having to wait for the caller to gather all possible candidates. This results in faster media setup in cases where gathering is not performed prior to initiating the call.

JSEP supports optional candidate trickling by providing APIs, as described above, that provide control and feedback on the ICE candidate gathering process. Applications that support candidate trickling can send the initial offer immediately and send individual candidates when they get notified of a new candidate; applications that do not support this feature can simply wait for the indication that gathering is complete, and then create and send their offer, with all the candidates, at that time.

Upon receipt of trickled candidates, the receiving application will supply them to its ICE agent. This triggers the ICE agent to start using the new remote candidates for connectivity checks.

3.5.2.1. ICE Candidate Format

In JSEP, ICE candidates are abstracted by an IceCandidate object, and as with session descriptions, SDP syntax is used for the internal representation.

The candidate details are specified in an IceCandidate field, using the same SDP syntax as the "candidate-attribute" field defined in [[RFC8839](#)], [Section 5.1](#). Note that this field does not contain an "a=" prefix, as indicated in the following example:

```
candidate:1 1 UDP 1694498815 192.0.2.33 10000 typ host
```

The IceCandidate object contains a field to indicate which ICE username fragment (ufrag) it is associated with, as defined in

[[RFC8839](#)], [Section 5.4](#). This value is used to determine which session description (and thereby which gathering phase) this IceCandidate belongs to, which helps resolve ambiguities during ICE restarts. If this field is absent in a received IceCandidate (perhaps when communicating with a non-JSEP endpoint), the most recently received session description is assumed.

The IceCandidate object also contains fields to indicate which "m=" section it is associated with, which can be identified in one of two ways: either by an "m=" section index or by a MID. The "m=" section index is a zero-based index, with index N referring to the N+1th "m=" section in the session description referenced by this IceCandidate. The MID is a "media stream identification" value, as defined in [[RFC5888](#)], [Section 4](#), which provides a more robust way to identify the "m=" section in the session description, using the MID of the associated RtpTransceiver object (which may have been locally generated by the answerer when interacting with a non-JSEP endpoint that does not support the MID attribute, as discussed in [Section 5.10](#) below). If the MID field is present in a received IceCandidate, it **MUST** be used for identification; otherwise, the "m=" section index is used instead.

Other than the "m=" section index, all IceCandidate fields are optional, and implementations **MUST NOT** reject a candidate simply because an optional field is missing.

3.5.3. ICE Candidate Policy

Typically, when gathering ICE candidates, the JSEP implementation will gather all possible forms of initial candidates -- host, server-reflexive, and relay. However, in certain cases, applications may want to have more specific control over the gathering process, due to privacy or related concerns. For example, one may want to only use relay candidates, to leak as little location information as possible (keeping in mind that this choice comes with corresponding operational costs). To accomplish this, JSEP allows the application to restrict which ICE candidates are used in a session. Note that this filtering is applied on top of any restrictions the implementation chooses to enforce regarding which IP addresses are permitted for the application, as discussed in [[RFC8828](#)].

There may also be cases where the application wants to change which types of candidates are used while the session is active. A prime example is where a callee may initially want to use only relay candidates, to avoid leaking location information to an arbitrary caller, but then change to use all candidates (for lower operational cost) once the user has indicated that they want to take the call. For this scenario, the JSEP implementation **MUST** allow the candidate

policy to be changed in mid-session, subject to the aforementioned interactions with local policy.

To administer the ICE candidate policy, the JSEP implementation will determine the current setting at the start of each gathering phase. Then, during the gathering phase, the implementation **MUST NOT** expose candidates disallowed by the current policy to the application, use them as the source of connectivity checks, or indirectly expose them via other fields, such as the raddr/rport attributes for other ICE candidates. Later, if a different policy is specified by the application, the application can apply it by kicking off a new gathering phase via an ICE restart.

3.5.4. ICE Candidate Pool

JSEP applications typically inform the JSEP implementation to begin ICE gathering via the information supplied to `setLocalDescription`, as the local description indicates the number of ICE components that will be needed and for which candidates must be gathered. However, to accelerate cases where the application knows the number of ICE components to use ahead of time, it may ask the implementation to gather a pool of potential ICE candidates to help ensure rapid media setup.

When `setLocalDescription` is eventually called and the JSEP implementation prepares to gather the needed ICE candidates, it **SHOULD** start by checking if any candidates are available in the pool. If there are candidates in the pool, they **SHOULD** be handed to the application immediately via the ICE candidate event. If the pool becomes depleted, either because a larger-than-expected number of ICE components are used or because the pool has not had enough time to gather candidates, the remaining candidates are gathered as usual. This only occurs for the first offer/answer exchange, after which the candidate pool is emptied and no longer used.

One example of where this concept is useful is an application that expects an incoming call at some point in the future, and wants to minimize the time it takes to establish connectivity, to avoid clipping of initial media. By pre-gathering candidates into the pool, it can exchange and start sending connectivity checks from these candidates almost immediately upon receipt of a call. Note, though, that by holding on to these pre-gathered candidates, which will be kept alive as long as they may be needed, the application will consume resources on the STUN/TURN servers it is using. ("STUN" stands for "Session Traversal Utilities for NAT".)

3.5.5. ICE Versions

While this specification formally relies on [RFC8445], at the time of its publication, the majority of WebRTC implementations support the version of ICE described in [RFC5245]. The "ice2" attribute defined in [RFC8445] can be used to detect the version in use by a remote endpoint and to provide a smooth transition from the older specification to the newer one. Implementations **MUST** be able to accept remote descriptions that do not have the "ice2" attribute.

3.6. Video Size Negotiation

Video size negotiation is the process through which a receiver can use the "a=imageattr" SDP attribute [RFC6236] to indicate what video frame sizes it is capable of receiving. A receiver may have hard limits on what its video decoder can process, or it may have some maximum set by policy. By specifying these limits in an "a=imageattr" attribute, JSEP endpoints can attempt to ensure that the remote sender transmits video at an acceptable resolution. However, when communicating with a non-JSEP endpoint that does not understand this attribute, any signaled limits may be exceeded, and the JSEP implementation **MUST** handle this gracefully, e.g., by discarding the video.

Note that certain codecs support transmission of samples with aspect ratios other than 1.0 (i.e., non-square pixels). JSEP implementations will not transmit non-square pixels but **SHOULD** receive and render such video with the correct aspect ratio. However, sample aspect ratio has no impact on the size negotiation described below; all dimensions are measured in pixels, whether square or not.

3.6.1. Creating an imageattr Attribute

The receiver will first combine any known local limits (e.g., hardware decoder capabilities or local policy) to determine the absolute minimum and maximum sizes it can receive. If there are no known local limits, the "a=imageattr" attribute **SHOULD** be omitted. If these local limits preclude receiving any video, i.e., the degenerate case of no permitted resolutions, the "a=imageattr" attribute **MUST** be omitted, and the "m=" section **MUST** be marked as sendonly/inactive, as appropriate.

Otherwise, an "a=imageattr" attribute is created with a "recv" direction, and the resulting resolution space formed from the aforementioned intersection is used to specify its minimum and maximum "x=" and "y=" values.

The rules here express a single set of preferences, and therefore, the "a=imageattr" "q=" value is not important. It **SHOULD** be set to "1.0".

The "a=imageattr" field is payload type specific. When all video codecs supported have the same capabilities, use of a single attribute, with the wildcard payload type (*), is **RECOMMENDED**. However, when the supported video codecs have different limitations, specific "a=imageattr" attributes **MUST** be inserted for each payload type.

As an example, consider a system with a multiformat video decoder, which is capable of decoding any resolution from 48x48 to 720p. In this case, the implementation would generate this attribute:

```
a=imageattr:* recv [x=[48:1280],y=[48:720],q=1.0]
```

This declaration indicates that the receiver is capable of decoding any image resolution from 48x48 up to 1280x720 pixels.

3.6.2. Interpreting imageattr Attributes

[[RFC6236](#)] defines "a=imageattr" to be an advisory field. This means that it does not absolutely constrain the video formats that the sender can use but gives an indication of the preferred values.

This specification prescribes behavior that is more specific. When a `MediaStreamTrack`, which is producing video of a certain resolution (the "track resolution"), is attached to an `RtpSender`, which is encoding the track video at the same or lower resolution(s) (the "encoder resolutions"), and a remote description is applied that references the sender and contains valid "a=imageattr recv" attributes, it **MUST** follow the rules below to ensure that the sender does not transmit a resolution that would exceed the size criteria specified in the attributes. These rules **MUST** be followed as long as the attributes remain present in the remote description, including cases in which the track changes its resolution or is replaced with a different track.

Depending on how the `RtpSender` is configured, it may be producing a single encoding at a certain resolution or, if simulcast ([Section 3.7](#)) has been negotiated, multiple encodings, each at their own specific resolution. In addition, depending on the configuration, each encoding may have the flexibility to reduce resolution when needed or may be locked to a specific output resolution.

For each encoding being produced by the `RtpSender`, the set of "a=imageattr recv" attributes in the corresponding "m=" section of the remote description is processed to determine what should be transmitted. Only attributes that reference the media format selected for the encoding are considered; each such attribute is evaluated individually, starting with the attribute with the highest "q=" value. If multiple attributes have the same "q=" value, they are evaluated in the order they appear in their containing "m=" section.

Note that while JSEP endpoints will include at most one "a=imageattr recv" attribute per media format, JSEP endpoints may receive session descriptions from non-JSEP endpoints with "m=" sections that contain multiple such attributes.

For each "a=imageattr recv" attribute, the following rules are applied. If this processing is successful, the encoding is transmitted accordingly, and no further attributes are considered for that encoding. Otherwise, the next attribute is evaluated, in the aforementioned order. If none of the supplied attributes can be processed successfully, the encoding **MUST NOT** be transmitted, and an error **SHOULD** be raised to the application.

- *The limits from the attribute are compared to the encoder resolution. Only the specific limits mentioned below are considered; any other values, such as picture aspect ratio, **MUST** be ignored. When considering a MediaStreamTrack that is producing rotated video, the unrotated resolution **MUST** be used for the checks. This is required regardless of whether the receiver supports performing receive-side rotation (e.g., through Coordination of Video Orientation (CVO) [[TS26.114](#)]), as it significantly simplifies the matching logic.
- *If the attribute includes a "sar=" (sample aspect ratio) value set to something other than "1.0", indicating that the receiver wants to receive non-square pixels, this cannot be satisfied and the attribute **MUST NOT** be used.
- *If the encoder resolution exceeds the maximum size permitted by the attribute and the encoder is allowed to adjust its resolution, the encoder **SHOULD** apply downscaling in order to satisfy the limits. Downscaling **MUST NOT** change the picture aspect ratio of the encoding, ignoring any trivial differences due to rounding. For example, if the encoder resolution is 1280x720 and the attribute specified a maximum of 640x480, the expected output resolution would be 640x360. If downscaling cannot be applied, the attribute **MUST NOT** be used.
- *If the encoder resolution is less than the minimum size permitted by the attribute, the attribute **MUST NOT** be used; the encoder **MUST NOT** apply upscaling. JSEP implementations **SHOULD** avoid this situation by allowing receipt of arbitrarily small resolutions, perhaps via fallback to a software decoder.
- *If the encoder resolution is within the maximum and minimum sizes, no action is needed.

3.7. Simulcast

JSEP supports simulcast transmission of a `MediaStreamTrack`, where multiple encodings of the source media can be transmitted within the context of a single "m=" section. The current JSEP API is designed to allow applications to send simulcasted media but only to receive a single encoding. This allows for multi-user scenarios where each sending client sends multiple encodings to a server, which then, for each receiving client, chooses the appropriate encoding to forward.

Applications request support for simulcast by configuring multiple encodings on an `RtpSender`. Upon generation of an offer or answer, these encodings are indicated via SDP markings on the corresponding "m=" section, as described below. Receivers that understand simulcast and are willing to receive it will also include SDP markings to indicate their support, and JSEP endpoints will use these markings to determine whether simulcast is permitted for a given `RtpSender`. If simulcast support is not negotiated, the `RtpSender` will only use the first configured encoding.

Note that the exact simulcast parameters are up to the sending application. While the aforementioned SDP markings are provided to ensure that the remote side can receive and demux multiple simulcast encodings, the specific resolutions and bitrates to be used for each encoding are purely a send-side decision in JSEP.

JSEP currently does not provide a mechanism to configure receipt of simulcast. This means that if simulcast is offered by the remote endpoint, the answer generated by a JSEP endpoint will not indicate support for receipt of simulcast, and as such the remote endpoint will only send a single encoding per "m=" section.

In addition, JSEP does not provide a mechanism to handle an incoming offer requesting simulcast from the JSEP endpoint. This means that setting up simulcast in the case where the JSEP endpoint receives the initial offer requires out-of-band signaling or SDP inspection. However, in the case where the JSEP endpoint sets up simulcast in its initial offer, any established simulcast streams will continue to work upon receipt of an incoming re-offer. Future versions of this specification may add additional APIs to handle the incoming initial offer scenario.

When using JSEP to transmit multiple encodings from an `RtpSender`, the techniques from [\[RFC8853\]](#) and [\[RFC8851\]](#) are used. Specifically, when multiple encodings have been configured for an `RtpSender`, the "m=" section for the `RtpSender` will include an "a=simulcast" attribute, as defined in [\[RFC8853\]](#), [Section 5.1](#), with a "send" simulcast stream description that lists each desired encoding, and no "recv" simulcast stream description. The "m=" section will also include an "a=rid"

attribute for each encoding, as specified in [[RFC8851](#)], [Section 4](#); the use of Restriction Identifiers (RIDs, also called rid-ids or RtpStreamIds) allows the individual encodings to be disambiguated even though they are all part of the same "m=" section.

3.8. Interactions with Forking

Some call signaling systems allow various types of forking where an SDP Offer may be provided to more than one device. For example, SIP [[RFC3261](#)] defines both a "parallel search" and "sequential search". Although these are primarily signaling-level issues that are outside the scope of JSEP, they do have some impact on the configuration of the media plane that is relevant. When forking happens at the signaling layer, the JavaScript application responsible for the signaling needs to make the decisions about what media should be sent or received at any point in time, as well as which remote endpoint it should communicate with; JSEP is used to make sure the media engine can make the RTP and media perform as required by the application. The basic operations that the applications can have the media engine do are as follows:

- *Start exchanging media with a given remote peer, but keep all the resources reserved in the offer.

- *Start exchanging media with a given remote peer, and free any resources in the offer that are not being used.

3.8.1. Sequential Forking

Sequential forking involves a call being dispatched to multiple remote callees, where each callee can accept the call, but only one active session ever exists at a time; no mixing of received media is performed.

JSEP handles sequential forking well, allowing the application to easily control the policy for selecting the desired remote endpoint. When an answer arrives from one of the callees, the application can choose to apply it as either (1) a provisional answer, leaving open the possibility of using a different answer in the future or (2) a final answer, ending the setup flow.

In a "first-one-wins" situation, the first answer will be applied as a final answer, and the application will reject any subsequent answers. In SIP parlance, this would be ACK + BYE.

In a "last-one-wins" situation, all answers would be applied as provisional answers, and any previous call leg will be terminated. At some point, the application will end the setup process, perhaps with a timer; at this point, the application could reapply the pending remote description as a final answer.

3.8.2. Parallel Forking

Parallel forking involves a call being dispatched to multiple remote callees, where each callee can accept the call and multiple simultaneous active signaling sessions can be established as a result. If multiple callees send media at the same time, the possibilities for handling this are described in [\[RFC3960\]](#), [Section 3.1](#). Most SIP devices today only support exchanging media with a single device at a time and do not try to mix multiple early media audio sources, as that could result in a confusing situation. For example, consider having a European ringback tone mixed together with the North American ringback tone -- the resulting sound would not be like either tone and would confuse the user. If the signaling application wishes to only exchange media with one of the remote endpoints at a time, then from a media engine point of view, this is exactly like the sequential forking case.

In the parallel forking case where the JavaScript application wishes to simultaneously exchange media with multiple peers, the flow is slightly more complex, but the JavaScript application can follow the strategy that [\[RFC3960\]](#) describes, using UPDATE. The UPDATE approach allows the signaling to set up a separate media flow for each peer that it wishes to exchange media with. In JSEP, this offer used in the UPDATE would be formed by simply creating a new PeerConnection (see [Section 4.1](#)) and making sure that the same local media streams have been added into this new PeerConnection. Then the new PeerConnection object would produce an SDP offer that could be used by the signaling to perform the UPDATE strategy discussed in [\[RFC3960\]](#).

As a result of sharing the media streams, the application will end up with N parallel PeerConnection sessions, each with a local and remote description and their own local and remote addresses. The media flow from these sessions can be managed using `setDirection` (see [Section 4.2.3](#)), or the application can choose to play out the media from all sessions mixed together. Of course, if the application wants to only keep a single session, it can simply terminate the sessions that it no longer needs.

4. Interface

This section details the basic operations that must be present to implement JSEP functionality. The actual API exposed in the W3C API may have somewhat different syntax but should map easily to these concepts.

4.1. PeerConnection

4.1.1. Constructor

The PeerConnection constructor allows the application to specify global parameters for the media session, such as the STUN/TURN servers and credentials to use when gathering candidates, as well as the initial ICE candidate policy and pool size, and also the bundle policy to use.

If an ICE candidate policy is specified, it functions as described in [Section 3.5.3](#), causing the JSEP implementation to only surface the permitted candidates (including any implementation-internal filtering) to the application and only use those candidates for connectivity checks. The set of available policies is as follows:

all: All candidates permitted by implementation policy will be gathered and used.

relay: All candidates except relay candidates will be filtered out. This obfuscates the location information that might be ascertained by the remote peer from the received candidates. Depending on how the application deploys and chooses relay servers, this could obfuscate location to a metro or possibly even global level.

The default ICE candidate policy **MUST** be set to "all", as this is generally the desired policy and also typically reduces the use of application TURN server resources significantly.

If a size is specified for the ICE candidate pool, this indicates the number of ICE components to pre-gather candidates for. Because pre-gathering results in utilizing STUN/TURN server resources for potentially long periods of time, this **MUST** only occur upon application request, and therefore the default candidate pool size **MUST** be zero.

The application can specify its preferred policy regarding the use of BUNDLE, the multiplexing mechanism defined in [[RFC9143](#)]. Regardless of policy, the application will always try to negotiate bundle onto a single transport and will offer a single bundle group across all "m=" sections; use of this single transport is contingent upon the answerer accepting bundle. However, by specifying a policy from the list below, the application can control exactly how aggressively it will try to bundle media streams together, which affects how it will interoperate with a non-bundle-aware endpoint. When negotiating with a non-bundle-aware endpoint, only the streams not marked as bundle-only streams will be established.

The set of available policies is as follows:

balanced:

The first "m=" section of each type (audio, video, or application) will contain transport parameters, which will allow an answerer to unbundle that section. The second and any subsequent "m=" sections of each type will be marked as bundle-only. The result is that if there are N distinct media types, then candidates will be gathered for N media streams. This policy balances the desire to multiplex with the need to ensure that basic audio and video can still be negotiated in legacy cases. When acting as answerer, if there is no bundle group in the offer, the implementation will reject all but the first "m=" section of each type.

max-compatible: All "m=" sections will contain transport parameters; none will be marked as bundle-only. This policy makes no assumptions about the remote endpoint and as such will allow all streams to be received by non-bundle-aware endpoints, but as a result requires separate candidates to be gathered for each media stream.

must-bundle: Only the first "m=" section will contain transport parameters; all streams other than the first will be marked as bundle-only. This policy presumes the remote endpoint supports multiplexing and accordingly aims to minimize candidate gathering, at the cost of less compatibility with legacy endpoints. When acting as answerer, the implementation will reject any "m=" sections other than the first "m=" section, unless they are in the same bundle group as that "m=" section.

As it provides the best trade-off between performance and compatibility with legacy endpoints, the default bundle policy **MUST** be set to "balanced".

[[RFC8829](#)] defined a policy known as "max-bundle", which, while defined identically to the "must-bundle" policy described above, was implemented by some implementations according to an earlier, pre-standard definition (in which, for example, no "m=" sections were marked as bundle-only). As a result, "max-bundle" is considered deprecated, and implementations compliant with this specification **SHOULD** ignore attempts by the application to select this bundle policy (although some phase-out period may be necessary to avoid application breakage).

The application can specify its preferred policy regarding use of RTP/RTCP multiplexing [[RFC5761](#)] using one of the following policies:

negotiate: The JSEP implementation will gather both RTP and RTCP candidates but also will offer "a=rtcp-mux", thus allowing for

compatibility with either multiplexing or non-multiplexing endpoints.

require: The JSEP implementation will only gather RTP candidates and will insert an "a=rtcp-mux-only" indication into any new "m=" sections in offers it generates. This halves the number of candidates that the offerer needs to gather. Applying a description with an "m=" section that does not contain an "a=rtcp-mux" attribute will cause an error to be returned.

The default multiplexing policy **MUST** be set to "require". Implementations **MAY** choose to reject attempts by the application to set the multiplexing policy to "negotiate".

4.1.2. addTrack

The addTrack method adds a MediaStreamTrack to the PeerConnection, using the MediaStream argument to associate the track with other tracks in the same MediaStream, so that they can be added to the same "LS" (Lip Synchronization) group when creating an offer or answer. Adding tracks to the same "LS" group indicates that the playback of these tracks should be synchronized for proper lip sync, as described in [[RFC5888](#)], [Section 7](#). addTrack attempts to minimize the number of transceivers as follows: if the PeerConnection is in the "have-remote-offer" state, the track will be attached to the first compatible transceiver that was created by the most recent call to setRemoteDescription and does not have a local track. Otherwise, a new transceiver will be created, as described in [Section 4.1.4](#).

4.1.3. removeTrack

The removeTrack method removes a MediaStreamTrack from the PeerConnection, using the RtpSender argument to indicate which sender should have its track removed. The sender's track is cleared, and the sender stops sending. Future calls to createOffer will mark the "m=" section associated with the sender as recvonly (if transceiver.direction is sendrecv) or as inactive (if transceiver.direction is sendonly).

4.1.4. addTransceiver

The addTransceiver method adds a new RtpTransceiver to the PeerConnection. If a MediaStreamTrack argument is provided, then the transceiver will be configured with that media type and the track will be attached to the transceiver. Otherwise, the application **MUST** explicitly specify the type; this mode is useful for creating recvonly transceivers as well as for creating transceivers to which a track can be attached at some later point.

At the time of creation, the application can also specify a transceiver direction attribute, a set of MediaStreams that the transceiver is associated with (allowing "LS" group assignments), and a set of encodings for the media (used for simulcast as described in [Section 3.7](#)).

4.1.5. onaddtrack Event

The onaddtrack event is dispatched to the application when a new remote track has been signaled as a result of a setRemoteDescription call. The new track is supplied as a MediaStreamTrack object in the event, along with the MediaStream(s) the track is part of.

4.1.6. createDataChannel

The createDataChannel method creates a new data channel and attaches it to the PeerConnection. If no data channel currently exists for this PeerConnection, then a new offer/answer exchange is required. All data channels on a given PeerConnection share the same SCTP/DTLS association ("SCTP" stands for "Stream Control Transmission Protocol") and therefore the same "m=" section, so subsequent creation of data channels does not have any impact on the JSEP state.

The createDataChannel method also includes a number of arguments that are used by the PeerConnection (e.g., maxPacketLifetime) but are not reflected in the SDP and do not affect the JSEP state.

4.1.7. ondatachannel Event

The ondatachannel event is dispatched to the application when a new data channel has been negotiated by the remote side, which can occur at any time after the underlying SCTP/DTLS association has been established. The new data channel object is supplied in the event.

4.1.8. createOffer

The createOffer method generates a blob of SDP that contains an offer per [\[RFC3264\]](#) with the configurations for the session that are supported by the application, including descriptions of the media added to this PeerConnection, the codec, RTP, and RTCP options supported by this implementation, and any candidates that have been gathered by the ICE agent. An options parameter may be supplied to provide additional control over the generated offer. This options parameter allows an application to trigger an ICE restart, for the purpose of reestablishing connectivity.

In the initial offer, the generated SDP will contain all desired functionality for the session (functionality that is supported but not desired by default may be omitted); for each SDP line, the generation of the SDP will follow the process defined for generating

an initial offer from the specification that defines the given SDP line. The exact handling of initial offer generation is detailed in [Section 5.2.1](#) below.

In the event `createOffer` is called after the session is established, `createOffer` will generate an offer to modify the current session based on any changes that have been made to the session, e.g., adding or stopping `RtpTransceivers`, or requesting an ICE restart. For each existing stream, the generation of each SDP line **MUST** follow the process defined for generating an updated offer from the RFC that specifies the given SDP line. For each new stream, the generation of the SDP **MUST** follow the process of generating an initial offer, as mentioned above. The exact handling of subsequent offer generation is detailed in [Section 5.2.2](#) below.

Session descriptions generated by `createOffer` **MUST** be immediately usable by `setLocalDescription`; if a system has limited resources (e.g., a finite number of decoders), `createOffer` **SHOULD** return an offer that reflects the current state of the system, so that `setLocalDescription` will succeed when it attempts to acquire those resources.

Calling this method may do things such as generating new ICE credentials, but it does not change the `PeerConnection` state, trigger candidate gathering, or cause media to start or stop flowing. Specifically, the offer is not applied, and does not become the pending local description, until `setLocalDescription` is called.

4.1.9. `createAnswer`

The `createAnswer` method generates a blob of SDP that contains an SDP answer per [[RFC3264](#)] with the supported configuration for the session that is compatible with the parameters supplied in the most recent call to `setRemoteDescription`; `setRemoteDescription` **MUST** have been called prior to calling `createAnswer`. Like `createOffer`, the returned blob contains descriptions of the media added to this `PeerConnection`, the codec, RTP, and RTCP options supported by the application, and any candidates that have been gathered by the ICE agent. An options parameter may be supplied to provide additional control over the generated answer.

As an answer, the generated SDP will contain a specific configuration that specifies how the media plane should be established; for each SDP line, the generation of the SDP **MUST** follow the process defined for generating an answer from the specification that defines the given SDP line. The exact handling of answer generation is detailed in [Section 5.3](#) below.

Session descriptions generated by `createAnswer` **MUST** be immediately usable by `setLocalDescription`; like `createOffer`, the returned description **SHOULD** reflect the current state of the system.

Calling this method may do things such as generating new ICE credentials, but it does not change the `PeerConnection` state, trigger candidate gathering, or cause a media state change. Specifically, the answer is not applied, and does not become the current local description, until `setLocalDescription` is called.

4.1.10. `SessionDescriptionType`

Session description objects (`RTCSessionDescription`) may be of type "offer", "pranswer", "answer", or "rollback". These types provide information as to how the description parameter should be parsed and how the media state should be changed.

"offer" indicates that a description **MUST** be parsed as an offer; said description may include many possible media configurations. A description used as an "offer" may be applied any time the `PeerConnection` is in a "stable" state or applied as an update to a previously supplied but unanswered "offer".

"pranswer" indicates that a description **MUST** be parsed as an answer, but not a final answer, and so **MUST NOT** result in the freeing of allocated resources. It may result in the start of media transmission, if the answer does not specify an inactive media direction. A description used as a "pranswer" may be applied as a response to an "offer" or as an update to a previously sent "pranswer".

"answer" indicates that a description **MUST** be parsed as an answer, the offer/answer exchange **MUST** be considered complete, and any resources (decoders, candidates) that are no longer needed **SHOULD** be released. A description used as an "answer" may be applied as a response to an "offer" or as an update to a previously sent "pranswer".

The only difference between a provisional and final answer is that the final answer results in the freeing of any unused resources that were allocated as a result of the offer. As such, the application can use some discretion on whether an answer should be applied as provisional or final and can change the type of the session description as needed. For example, in a serial forking scenario, an application may receive multiple "final" answers, one from each remote endpoint. The application could choose to accept the initial answers as provisional answers and only apply an answer as final when it receives one that meets its criteria (e.g., a live user instead of voicemail).

"rollback" is a special session description type indicating that the state machine **MUST** be rolled back to the previous "stable" state, as described in [Section 4.1.10.2](#). The contents **MUST** be empty.

4.1.10.1. Use of Provisional Answers

Most applications will not need to create answers using the "pranswer" type. While it is good practice to send an immediate response to an offer, in order to warm up the session transport and prevent media clipping, the preferred handling for a JSEP application is to create and send a "sendonly" final answer with a null `MediaStreamTrack` immediately after receiving the offer, which will prevent media from being sent by the caller and allow media to be sent immediately upon answer by the callee. Later, when the callee actually accepts the call, the application can plug in the real `MediaStreamTrack` and create a new "sendrecv" offer to update the previous offer/answer pair and start bidirectional media flow. While this could also be done with a "sendonly" pranswer followed by a "sendrecv" answer, the initial pranswer leaves the offer/answer exchange open, which means that the caller cannot send an updated offer during this time.

As an example, consider a typical JSEP application that wants to set up audio and video as quickly as possible. When the callee receives an offer with audio and video `MediaStreamTracks`, it will send an immediate answer accepting these tracks as sendonly (meaning that the caller will not send the callee any media yet, and because the callee has not yet added its own `MediaStreamTracks`, the callee will not send any media either). It will then ask the user to accept the call and acquire the needed local tracks. Upon acceptance by the user, the application will plug in the tracks it has acquired, which, because ICE handshaking and DTLS handshaking have likely completed by this point, can start transmitting immediately. The application will also send a new offer to the remote side indicating call acceptance and moving the audio and video to be two-way media. A detailed example flow along these lines is shown in [Section 7.3](#).

Of course, some applications may not be able to perform this double offer/answer exchange, particularly ones that are attempting to gateway to legacy signaling protocols. In these cases, pranswer can still provide the application with a mechanism to warm up the transport.

4.1.10.2. Rollback

In certain situations, it may be desirable to "undo" a change made to `setLocalDescription` or `setRemoteDescription`. Consider a case where a call is ongoing and one side wants to change some of the session parameters; that side generates an updated offer and then calls

setLocalDescription. However, the remote side, either before or after setRemoteDescription, decides it does not want to accept the new parameters and sends a reject message back to the offerer. Now, the offerer, and possibly the answerer as well, needs to return to a "stable" state and the previous local/remote description. To support this, this specification introduces the concept of "rollback", which discards any proposed changes to the session, returning the state machine to the "stable" state. A rollback is performed by supplying a session description of type "rollback" with empty contents to either setLocalDescription or setRemoteDescription.

4.1.11. setLocalDescription

The setLocalDescription method instructs the PeerConnection to apply the supplied session description as its local configuration. The type field indicates whether the description should be processed as an offer, provisional answer, final answer, or rollback; offers and answers are checked differently, using the various rules that exist for each SDP line.

This API changes the local media state; among other things, it sets up local resources for receiving and decoding media. In order to successfully handle scenarios where the application wants to offer to change from one media format to a different, incompatible format, the PeerConnection **MUST** be able to simultaneously support use of both the current and pending local descriptions (e.g., support the codecs that exist in either description). This dual processing begins when the PeerConnection enters the "have-local-offer" state, and it continues until setRemoteDescription is called with either (1) a final answer, at which point the PeerConnection can fully adopt the pending local description or (2) a rollback, which results in a revert to the current local description.

This API indirectly controls the candidate gathering process. When a local description is supplied and the number of transports currently in use does not match the number of transports needed by the local description, the PeerConnection will create transports as needed and begin gathering candidates for each transport, using ones from the candidate pool if available.

If (1) setRemoteDescription was previously called with an offer, (2) setLocalDescription is called with an answer (provisional or final), (3) the media directions are compatible, and (4) media is available to send, this will result in the starting of media transmission.

4.1.12. setRemoteDescription

The setRemoteDescription method instructs the PeerConnection to apply the supplied session description as the desired remote configuration.

As in `setLocalDescription`, the `type` field of the description indicates how it should be processed.

This API changes the local media state; among other things, it sets up local resources for sending and encoding media.

If (1) `setLocalDescription` was previously called with an offer, (2) `setRemoteDescription` is called with an answer (provisional or final), (3) the media directions are compatible, and (4) media is available to send, this will result in the starting of media transmission.

4.1.13. `currentLocalDescription`

The `currentLocalDescription` method returns the current negotiated local description -- i.e., the local description from the last successful offer/answer exchange -- in addition to any local candidates that have been generated by the ICE agent since the local description was set.

A null object will be returned if an offer/answer exchange has not yet been completed.

4.1.14. `pendingLocalDescription`

The `pendingLocalDescription` method returns a copy of the local description currently in negotiation -- i.e., a local offer set without any corresponding remote answer -- in addition to any local candidates that have been generated by the ICE agent since the local description was set.

A null object will be returned if the state of the `PeerConnection` is "stable" or "have-remote-offer".

4.1.15. `currentRemoteDescription`

The `currentRemoteDescription` method returns a copy of the current negotiated remote description -- i.e., the remote description from the last successful offer/answer exchange -- in addition to any remote candidates that have been supplied via `processIceMessage` since the remote description was set.

A null object will be returned if an offer/answer exchange has not yet been completed.

4.1.16. `pendingRemoteDescription`

The `pendingRemoteDescription` method returns a copy of the remote description currently in negotiation -- i.e., a remote offer set without any corresponding local answer -- in addition to any remote

candidates that have been supplied via `processIceMessage` since the remote description was set.

A null object will be returned if the state of the `PeerConnection` is "stable" or "have-local-offer".

4.1.17. `canTrickleIceCandidates`

The `canTrickleIceCandidates` property indicates whether the remote side supports receiving trickled candidates. There are three potential values:

null: No SDP has been received from the other side, so it is not known if it can handle trickle. This is the initial value before `setRemoteDescription` is called.

true: SDP has been received from the other side indicating that it can support trickle.

false: SDP has been received from the other side indicating that it cannot support trickle.

As described in [Section 3.5.2](#), JSEP implementations always provide candidates to the application individually, consistent with what is needed for Trickle ICE. However, applications can use the `canTrickleIceCandidates` property to determine whether their peer can actually do Trickle ICE, i.e., whether it is safe to send an initial offer or answer followed later by candidates as they are gathered. As "true" is the only value that definitively indicates remote Trickle ICE support, an application that compares `canTrickleIceCandidates` against "true" will by default attempt Half Trickle on initial offers and Full Trickle on subsequent interactions with a Trickle ICE-compatible agent.

4.1.18. `setConfiguration`

The `setConfiguration` method allows the global configuration of the `PeerConnection`, which was initially set by constructor parameters, to be changed during the session. The effects of calling this method depend on when it is invoked, and they will differ, depending on which specific parameters are changed:

*Any changes to the STUN/TURN servers to use affect the next gathering phase. If an ICE gathering phase has already started or completed, the 'needs-ice-restart' bit mentioned in [Section 3.5.1](#) will be set. This will cause the next call to `createOffer` to generate new ICE credentials, for the purpose of forcing an ICE restart and kicking off a new gathering phase, in which the new servers will be used. If the ICE candidate pool has a nonzero size and a local description has not yet been applied, any existing

candidates will be discarded, and new candidates will be gathered from the new servers.

*Any change to the ICE candidate policy affects the next gathering phase. If an ICE gathering phase has already started or completed, the 'needs-ice-restart' bit will be set. Either way, changes to the policy have no effect on the candidate pool, because pooled candidates are not made available to the application until a gathering phase occurs, and so any necessary filtering can still be done on any pooled candidates.

*The ICE candidate pool size **MUST NOT** be changed after applying a local description. If a local description has not yet been applied, any changes to the ICE candidate pool size take effect immediately; if increased, additional candidates are pre-gathered; if decreased, the now-superfluous candidates are discarded.

*The bundle and RTCP-multiplexing policies **MUST NOT** be changed after the construction of the PeerConnection.

Calling this method may result in a change to the state of the ICE agent.

4.1.19. addIceCandidate

The addIceCandidate method provides an update to the ICE agent via an IceCandidate object ([Section 3.5.2.1](#)). If the IceCandidate's candidate field is non-null, the IceCandidate is treated as a new remote ICE candidate, which will be added to the current and/or pending remote description according to the rules defined for Trickle ICE. Otherwise, the IceCandidate is treated as an end-of-candidates indication, as defined in [[RFC8838](#)], [Section 14](#).

In either case, the "m=" section index, MID, and ufrag fields from the supplied IceCandidate are used to determine which "m=" section and ICE candidate generation the IceCandidate belongs to, as described in [Section 3.5.2.1](#) above. In the case of an end-of-candidates indication, null values for the "m=" section index and MID fields are interpreted to mean that the indication applies to all "m=" sections in the specified ICE candidate generation. However, if both fields are null for a new remote candidate, this **MUST** be treated as an invalid condition, as specified below.

If any IceCandidate fields contain invalid values or an error occurs during the processing of the IceCandidate object, the supplied IceCandidate **MUST** be ignored and an error **MUST** be returned.

Otherwise, the new remote candidate or end-of-candidates indication is supplied to the ICE agent. In the case of a new remote candidate, connectivity checks will be sent to the new candidate, assuming

setLocalDescription has already been called to initialize the ICE gathering process.

4.1.20. onicecandidate Event

The onicecandidate event is dispatched to the application in two situations: (1) when the ICE agent has discovered a new allowed local ICE candidate during ICE gathering, as outlined in [Section 3.5.1](#) and subject to the restrictions discussed in [Section 3.5.3](#), or (2) when an ICE gathering phase completes. The event contains a single IceCandidate object, as defined in [Section 3.5.2.1](#).

In the first case, the newly discovered candidate is reflected in the IceCandidate object, and all of its fields **MUST** be non-null. This candidate will also be added to the current and/or pending local description according to the rules defined for Trickle ICE.

In the second case, the event's IceCandidate object **MUST** have its candidate field set to null to indicate that the current gathering phase is complete, i.e., there will be no further onicecandidate events in this phase. However, the IceCandidate's ufrag field **MUST** be specified to indicate which ICE candidate generation is ending. The IceCandidate's "m=" section index and MID fields **MAY** be specified to indicate that the event applies to a specific "m=" section, or set to null to indicate it applies to all "m=" sections in the current ICE candidate generation. This event can be used by the application to generate an end-of-candidates indication, as defined in [[RFC8838](#)], [Section 13](#).

4.2. RtpTransceiver

4.2.1. stop

The stop method stops an RtpTransceiver. This will cause future calls to createOffer to generate a zero port for the associated "m=" section. See below for more details.

4.2.2. stopped

The stopped property indicates whether the transceiver has been stopped, either by a call to stop or by applying an answer that rejects the associated "m=" section. In either of these cases, it is set to "true" and otherwise will be set to "false".

A stopped RtpTransceiver does not send any outgoing RTP or RTCP or process any incoming RTP or RTCP. It cannot be restarted.

4.2.3. setDirection

The setDirection method sets the direction of a transceiver, which affects the direction property of the associated "m=" section on future calls to createOffer and createAnswer. The permitted values for direction are "recvonly", "sendrecv", "sendonly", and "inactive", mirroring the identically named direction attributes defined in [\[RFC4566\]](#), [Section 6](#).

When creating offers, the transceiver direction is directly reflected in the output, even for re-offers. When creating answers, the transceiver direction is intersected with the offered direction, as explained in [Section 5.3](#) below.

Note that while setDirection sets the direction property of the transceiver immediately ([Section 4.2.4](#)), this property does not immediately affect whether the transceiver's RtpSender will send or its RtpReceiver will receive. The direction in effect is represented by the currentDirection property, which is only updated when an answer is applied.

4.2.4. direction

The direction property indicates the last value passed into setDirection. If setDirection has never been called, it is set to the direction the transceiver was initialized with.

4.2.5. currentDirection

The currentDirection property indicates the last negotiated direction for the transceiver's associated "m=" section. More specifically, it indicates the direction attribute [\[RFC3264\]](#) of the associated "m=" section in the last applied answer (including provisional answers), with "send" and "recv" directions reversed if it was a remote answer. For example, if the direction attribute for the associated "m=" section in a remote answer is "recvonly", currentDirection is set to "sendonly".

If an answer that references this transceiver has not yet been applied or if the transceiver is stopped, currentDirection is set to "null".

4.2.6. setCodecPreferences

The setCodecPreferences method sets the codec preferences of a transceiver, which in turn affect the presence and order of codecs of the associated "m=" section on future calls to createOffer and createAnswer. Note that setCodecPreferences does not directly affect which codec the implementation decides to send. It only affects which codecs the implementation indicates that it prefers to receive, via

the offer or answer. Even when a codec is excluded by `setCodecPreferences`, it still may be used to send until the next offer/answer exchange discards it.

The codec preferences of an `RtpTransceiver` can cause codecs to be excluded by subsequent calls to `createOffer` and `createAnswer`, in which case the corresponding media formats in the associated "m=" section will be excluded. The codec preferences cannot add media formats that would otherwise not be present.

The codec preferences of an `RtpTransceiver` can also determine the order of codecs in subsequent calls to `createOffer` and `createAnswer`, in which case the order of the media formats in the associated "m=" section will follow the specified preferences.

5. SDP Interaction Procedures

This section describes the specific procedures to be followed when creating and parsing SDP objects.

5.1. Requirements Overview

JSEP implementations **MUST** comply with the specifications listed below that govern the creation and processing of offers and answers.

5.1.1. Usage Requirements

All session descriptions handled by JSEP implementations, both local and remote, **MUST** indicate support for the following specifications. If any of these are absent, this omission **MUST** be treated as an error.

*ICE, as specified in [[RFC8445](#)], **MUST** be used. Note that the remote endpoint may use a lite implementation; implementations **MUST** properly handle remote endpoints that use ICE-lite. The remote endpoint may also use an older version of ICE; implementations **MUST** properly handle remote endpoints that use ICE as specified in [[RFC5245](#)].

*DTLS [[RFC6347](#)] or DTLS-SRTP [[RFC5763](#)] **MUST** be used, as appropriate for the media type, as specified in [[RFC8827](#)].

The SDP security descriptions mechanism for SRTP keying [[RFC4568](#)] **MUST NOT** be used, as discussed in [[RFC8827](#)].

5.1.2. Profile Names and Interoperability

For media "m=" sections, JSEP implementations **MUST** support the "UDP/TLS/RTP/SAVPF" profile specified in [[RFC5764](#)] as well as the "TCP/DTLS/RTP/SAVPF" profile specified in [[RFC7850](#)] and **MUST** indicate one

of these profiles for each media "m=" line they produce in an offer. For data "m=" sections, implementations **MUST** support the "UDP/DTLS/SCTP" profile as well as the "TCP/DTLS/SCTP" profile and **MUST** indicate one of these profiles for each data "m=" line they produce in an offer. The exact profile to use is determined by the protocol associated with the current default or selected ICE candidate, as described in [[RFC8839](#)], [Section 4.2.1.2](#).

Unfortunately, in an attempt at compatibility, some endpoints generate other profile strings even when they mean to support one of these profiles. For instance, an endpoint might generate "RTP/AVP" but supply "a=fingerprint" and "a=rtcp-fb" attributes, indicating its willingness to support "UDP/TLS/RTP/SAVPF" or "TCP/DTLS/RTP/SAVPF". In order to simplify compatibility with such endpoints, JSEP implementations **MUST** follow the following rules when processing the media "m=" sections in a received offer:

*Any profile in the offer matching one of the following **MUST** be accepted:

- "RTP/AVP" (defined in [[RFC4566](#)], [Section 8.2.2](#))
- "RTP/AVPF" (defined in [[RFC4585](#)], [Section 9](#))
- "RTP/SAVP" (defined in [[RFC3711](#)], [Section 12](#))
- "RTP/SAVPF" (defined in [[RFC5124](#)], [Section 6](#))
- "TCP/DTLS/RTP/SAVP" (defined in [[RFC7850](#)], [Section 3.4](#))
- "TCP/DTLS/RTP/SAVPF" (defined in [[RFC7850](#)], [Section 3.5](#))
- "UDP/TLS/RTP/SAVP" (defined in [[RFC5764](#)], [Section 9](#))
- "UDP/TLS/RTP/SAVPF" (defined in [[RFC5764](#)], [Section 9](#))

*The profile in any "m=" line in any generated answer **MUST** exactly match the profile provided in the offer.

*Because DTLS-SRTP is **REQUIRED**, the choice of SAVP or AVP has no effect; support for DTLS-SRTP is determined by the presence of one or more "a=fingerprint" attributes. Note that lack of an "a=fingerprint" attribute will lead to negotiation failure.

*The use of AVPF or AVP simply controls the timing rules used for RTCP feedback. If AVPF is provided or an "a=rtcp-fb" attribute is present, assume AVPF timing, i.e., a default value of "trr-int=0". Otherwise, assume that AVPF is being used in an AVP-compatible mode and use a value of "trr-int=4000".

*For data "m=" sections, implementations **MUST** support receiving the "UDP/DTLS/SCTP", "TCP/DTLS/SCTP", or "DTLS/SCTP" (for backwards compatibility) profiles.

Note that re-offers by JSEP implementations **MUST** use the correct profile strings even if the initial offer/answer exchange used an (incorrect) older profile string. This simplifies JSEP behavior, with minimal downside, as any remote endpoint that fails to handle such a re-offer will also fail to handle a JSEP endpoint's initial offer.

5.2. Constructing an Offer

When createOffer is called, a new SDP description **MUST** be created that includes the functionality specified in [RFC8834]. The exact details of this process are explained below.

5.2.1. Initial Offers

When createOffer is called for the first time, the result is known as the initial offer.

The first step in generating an initial offer is to generate session-level attributes, as specified in [RFC4566], [Section 5](#). Specifically:

*The first SDP line **MUST** be "v=0" as defined in [RFC4566], [Section 5.1](#).

*The second SDP line **MUST** be an "o=" line as defined in [RFC4566], [Section 5.2](#). The value of the <username> field **SHOULD** be "-". The <sess-id> **MUST** be representable by a 64-bit signed integer, and the value **MUST** be less than $2^{63}-1$. This is to ensure that the <sess-id> value, when expressed as a string, is always a non-negative integer, as some SDP parsers may fail to parse a negative <sess-id>. It is **RECOMMENDED** that the <sess-id> be constructed by generating a 64-bit quantity with the highest bit set to zero and the remaining 63 bits being cryptographically random. The value of the <nettype> <addrtype> <unicast-address> tuple **SHOULD** be set to a non-meaningful address, such as IN IP4 0.0.0.0, to prevent leaking a local IP address in this field; this problem is discussed in [RFC8828]. As mentioned in [RFC4566], the entire "o=" line needs to be unique, but selecting a random number for <sess-id> is sufficient to accomplish this.

*The third SDP line **MUST** be a "s=" line as defined in [RFC4566], [Section 5.3](#); to match the "o=" line, a single dash **SHOULD** be used as the session name, e.g., "s=-". Note that this differs from the advice in [RFC4566], which proposes a single space, but as both "o=" and "s=" are meaningless in JSEP, having the same meaningless value seems clearer.

*Session Information ("i="), URI ("u="), Email Address ("e="), Phone Number ("p="), Repeat Times ("r="), and Time Zones ("z=") lines are not useful in this context and **SHOULD NOT** be included.

*Encryption Keys ("k=") lines do not provide sufficient security and **MUST NOT** be included.

*A "t=" line **MUST** be added, as specified in [[RFC4566](#)], [Section 5.9](#); both <start-time> and <stop-time> **SHOULD** be set to zero, e.g., "t=0 0".

*An "a=ice-options" line with the "trickle" and "ice2" options **MUST** be added, as specified in [[RFC8840](#)], [Section 4.1.1](#) and [[RFC8445](#)], [Section 10](#).

*If WebRTC identity is being used, an "a=identity" line **MUST** be added, as described in [[RFC8827](#)], [Section 5](#).

The next step is to generate "m=" sections, as specified in [[RFC4566](#)], [Section 5.14](#). An "m=" section is generated for each RtpTransceiver that has been added to the PeerConnection, excluding any stopped RtpTransceivers; this is done in the order the RtpTransceivers were added to the PeerConnection. If there are no such RtpTransceivers, no "m=" sections are generated; more can be added later, as discussed in [[RFC3264](#)], [Section 5](#).

For each "m=" section generated for an RtpTransceiver, establish a mapping between the transceiver and the index of the generated "m=" section.

Each "m=" section, provided it is not marked as bundle-only, **MUST** contain a unique set of ICE credentials and a unique set of ICE candidates. Bundle-only "m=" sections **MUST NOT** contain any ICE credentials and **MUST NOT** gather any candidates.

For DTLS, all "m=" sections **MUST** use any and all certificates that have been specified for the PeerConnection; as a result, they **MUST** all have the same fingerprint value or values [[RFC8122](#)], or these values **MUST** be session-level attributes.

Each "m=" section **MUST** be generated as specified in [[RFC4566](#)], [Section 5.14](#). For the "m=" line itself, the following rules **MUST** be followed:

*If the "m=" section is marked as bundle-only, then the <port> value **MUST** be set to zero. Otherwise, the <port> value is set to the port of the default ICE candidate for this "m=" section, but given that no candidates are available yet, the default port value of 9 (Discard) **MUST** be used, as indicated in [[RFC8840](#)], [Section 4.1.1](#).

*To properly indicate use of DTLS, the <proto> field **MUST** be set to "UDP/TLS/RTP/SAVPF", as specified in [[RFC5764](#)], [Section 8](#).

*If codec preferences have been set for the associated transceiver, media formats **MUST** be generated in the corresponding order and **MUST** exclude any codecs not present in the codec preferences.

*Unless excluded by the above restrictions, the media formats **MUST** include the mandatory audio/video codecs as specified in [[RFC7874](#)], [Section 3](#) and [[RFC7742](#)], [Section 5](#).

The "m=" line **MUST** be followed immediately by a "c=" line, as specified in [[RFC4566](#)], [Section 5.7](#). Again, as no candidates are available yet, the "c=" line **MUST** contain the default value "IN IP4 0.0.0.0", as defined in [[RFC8840](#)], [Section 4.1.1](#).

[[RFC8859](#)] groups SDP attributes into different categories. To avoid unnecessary duplication when bundling, attributes of category IDENTICAL or TRANSPORT **MUST NOT** be repeated in bundled "m=" sections, repeating the guidance from [[RFC9143](#)], [Section 7.1.3](#). This includes "m=" sections for which bundling has been negotiated and is still desired, as well as "m=" sections marked as bundle-only.

The following attributes, which are of a category other than IDENTICAL or TRANSPORT, **MUST** be included in each "m=" section:

*An "a=mid" line, as specified in [[RFC5888](#)], [Section 4](#). All MID values **MUST** be generated in a fashion that does not leak user information, e.g., randomly or using a per-PeerConnection counter, and **SHOULD** be 3 bytes or less, to allow them to efficiently fit into the RTP header extension defined in [[RFC9143](#)], [Section 15.2](#). Note that this does not set the RtpTransceiver mid property, as that only occurs when the description is applied. The generated MID value can be considered a "proposed" MID at this point.

*A direction attribute that is the same as that of the associated transceiver.

*For each media format on the "m=" line, "a=rtpmap" and "a=fmtp" lines, as specified in [[RFC4566](#)], [Section 6](#) and [[RFC3264](#)], [Section 5.1](#).

*For each primary codec where RTP retransmission should be used, a corresponding "a=rtpmap" line indicating "rtx" with the clock rate of the primary codec and an "a=fmtp" line that references the payload type of the primary codec, as specified in [[RFC4588](#)], [Section 8.1](#).

*For each Forward Error Correction (FEC) mechanism supported by the application, "a=rtpmap" and "a=fmtp" lines, as specified in

[RFC4566], [Section 6](#). The FEC mechanisms that **MUST** be supported are specified in [RFC8854], [Section 7](#), and specific usage for each media type is outlined in [Sections 4](#) and [5](#).

- *If this "m=" section is for media with configurable durations of media per packet, e.g., audio, an "a=maxptime" line, indicating the maximum amount of media, specified in milliseconds, that can be encapsulated in each packet, as specified in [RFC4566], [Section 6](#). This value is set to the smallest of the maximum duration values across all the codecs included in the "m=" section.
- *If this "m=" section is for video media and there are known limitations on the size of images that can be decoded, an "a=imageattr" line, as specified in [Section 3.6](#).
- *For each RTP header extension supported by the application, an "a=extmap" line, as specified in [RFC5285], [Section 5](#). The list of header extensions that **SHOULD/MUST** be supported is specified in [RFC8834], [Section 5.2](#). Any header extensions that require encryption **MUST** be specified as indicated in [RFC6904], [Section 4](#).
- *For each RTCP feedback mechanism supported by the application, an "a=rtcp-fb" line, as specified in [RFC4585], [Section 4.2](#). The list of RTCP feedback mechanisms that **SHOULD/MUST** be supported is specified in [RFC8834], [Section 5.1](#).
- *If the RtpTransceiver has a sendrecv or sendonly direction:
 - For each MediaStream that was associated with the transceiver when it was created via addTrack or addTransceiver, an "a=msid" line, as specified in [RFC8830], [Section 2](#), but omitting the "appdata" field.
- *If the RtpTransceiver has a sendrecv or sendonly direction, and the application has specified a rid-id for an encoding, or has specified more than one encoding in the RtpSenders's parameters, an "a=rid" line for each encoding specified. The "a=rid" line is specified in [RFC8851], and its direction **MUST** be "send". If the application has chosen a rid-id, it **MUST** be used; otherwise, a rid-id **MUST** be generated by the implementation. rid-ids **MUST** be generated in a fashion that does not leak user information, e.g., randomly or using a per-PeerConnection counter (see guidance at the end of [RFC8852], [Section 3.3](#)), and **SHOULD** be 3 bytes or less, to allow them to efficiently fit into the RTP header extensions defined in [RFC8852], [Section 3.3](#). If no encodings have been specified, or only one encoding is specified but without a rid-id, then no "a=rid" lines are generated.

*If the RtpTransceiver has a sendrecv or sendonly direction and more than one "a=rid" line has been generated, an "a=simulcast" line, with direction "send", as defined in [[RFC8853](#)], [Section 5.1](#). The associated set of rid-ids **MUST** include all of the rid-ids used in the "a=rid" lines for this "m=" section.

*If (1) the bundle policy for this PeerConnection is set to "must-bundle" and this is not the first "m=" section or (2) the bundle policy is set to "balanced" and this is not the first "m=" section for this media type, an "a=bundle-only" line.

The following attributes, which are of category IDENTICAL or TRANSPORT, **MUST** appear only in "m=" sections that either have a unique address or are associated with the BUNDLE-tag. (In initial offers, this means those "m=" sections that do not contain an "a=bundle-only" attribute.)

*"a=ice-ufrag" and "a=ice-pwd" lines, as specified in [[RFC8839](#)], [Section 5.4](#).

*For each desired digest algorithm, one or more "a=fingerprint" lines for each of the endpoint's certificates, as specified in [[RFC8122](#)], [Section 5](#).

*An "a=setup" line, as specified in [[RFC4145](#)], [Section 4](#) and clarified for use in DTLS-SRTP scenarios in [[RFC5763](#)], [Section 5](#). The role value in the offer **MUST** be "actpass".

*An "a=tls-id" line, as specified in [[RFC8842](#)], [Section 5.2](#).

*An "a=rtcp" line, as specified in [[RFC3605](#)], [Section 2.1](#), containing the default value "9 IN IP4 0.0.0.0", because no candidates have yet been gathered.

*An "a=rtcp-mux" line, as specified in [[RFC5761](#)], [Section 5.1.3](#).

*If the RTP/RTCP multiplexing policy is "require", an "a=rtcp-mux-only" line, as specified in [[RFC8858](#)], [Section 4](#).

*An "a=rtcp-rsize" line, as specified in [[RFC5506](#)], [Section 5](#).

Lastly, if a data channel has been created, an "m=" section **MUST** be generated for data. The <media> field **MUST** be set to "application", and the <proto> field **MUST** be set to "UDP/DTLS/SCTP" [[RFC8841](#)]. The <fmt> value **MUST** be set to "webrtc-datachannel" as specified in [[RFC8841](#)], [Section 4.2.2](#).

Within the data "m=" section, an "a=mid" line **MUST** be generated and included as described above, along with an "a=sctp-port" line referencing the SCTP port number, as defined in [[RFC8841](#)],

[Section 5.1](#); and, if appropriate, an "a=max-message-size" line, as defined in [[RFC8841](#)], [Section 6.1](#).

As discussed above, the following attributes of category IDENTICAL or TRANSPORT are included only if the data "m=" section either has a unique address or is associated with the BUNDLE-tag (e.g., if it is the only "m=" section):

```
*"a=ice-ufrag"  
  
*"a=ice-pwd"  
  
*"a=fingerprint"  
  
*"a=setup"  
  
*"a=tls-id"
```

Once all "m=" sections have been generated, a session-level "a=group" attribute **MUST** be added as specified in [[RFC5888](#)]. This attribute **MUST** have semantics "BUNDLE" and **MUST** include the mid identifiers of each "m=" section. The effect of this is that the JSEP implementation offers all "m=" sections as one bundle group. However, whether the "m=" sections are bundle-only or not depends on the bundle policy.

The next step is to generate session-level lip sync groups as defined in [[RFC5888](#)], [Section 7](#). For each MediaStream referenced by more than one RtpTransceiver (by passing those MediaStreams as arguments to the addTrack and addTransceiver methods), a group of type "LS" **MUST** be added that contains the MID values for each RtpTransceiver.

Attributes that SDP permits to be at either the session level or the media level **SHOULD** generally be at the media level even if they are identical. This assists development and debugging by making it easier to understand individual media sections, especially if one of a set of initially identical attributes is subsequently changed. However, implementations **MAY** choose to aggregate attributes at the session level, and JSEP implementations **MUST** be prepared to receive attributes in either location.

Attributes other than the ones specified above **MAY** be included, except for the following attributes, which are specifically incompatible with the requirements of [[RFC8834](#)] and **MUST NOT** be included:

```
*"a=crypto"  
  
*"a=key-mgmt"  
  
*"a=ice-lite"
```

Note that when bundle is used, any additional attributes that are added **MUST** follow the advice in [[RFC8859](#)] on how those attributes interact with bundle.

Note that these requirements are in some cases stricter than those of SDP. Implementations **MUST** be prepared to accept compliant SDP even if it would not conform to the requirements for generating SDP in this specification.

5.2.2. Subsequent Offers

When createOffer is called a second (or later) time or is called after a local description has already been installed, the processing is somewhat different than for an initial offer.

If the previous offer was not applied using setLocalDescription, meaning the PeerConnection is still in the "stable" state, the steps for generating an initial offer **MUST** be followed, subject to the following restriction:

- *The fields of the "o=" line **MUST** stay the same except for the <session-version> field, which **MUST** increment by one on each call to createOffer if the offer might differ from the output of the previous call to createOffer; implementations **MAY** opt to increment <session-version> on every call. The value of the generated <session-version> is independent of the <session-version> of the current local description; in particular, in the case where the current version is N, an offer is created and applied with version N+1, and then that offer is rolled back so that the current version is again N, the next generated offer will still have version N+2.

Note that if the application creates an offer by reading currentLocalDescription instead of calling createOffer, the returned SDP may be different than when setLocalDescription was originally called, due to the addition of gathered ICE candidates, but the <session-version> will not have changed. There are no known scenarios in which this causes problems, but if this is a concern, the solution is simply to use createOffer to ensure a unique <session-version>.

If the previous offer was applied using setLocalDescription, but a corresponding answer from the remote side has not yet been applied, meaning the PeerConnection is still in the "have-local-offer" state, an offer is generated by following the steps in the "stable" state above, along with these exceptions:

- *The "s=" and "t=" lines **MUST** stay the same.

- *If any RtpTransceiver has been added and there exists an "m=" section with a zero port in the current local description or the

current remote description, that "m=" section **MUST** be recycled by generating an "m=" section for the added RtpTransceiver as if the "m=" section were being added to the session description (including a new MID value) and placing it at the same index as the "m=" section with a zero port.

*If an RtpTransceiver is stopped and is not associated with an "m=" section, an "m=" section **MUST NOT** be generated for it. This prevents adding back RtpTransceivers whose "m=" sections were recycled and used for a new RtpTransceiver in a previous offer/answer exchange, as described above.

*If an RtpTransceiver has been stopped and is associated with an "m=" section, and the "m=" section is not being recycled as described above, an "m=" section **MUST** be generated for it with the port set to zero and all "a=msid" lines removed.

*For RtpTransceivers that are not stopped, the "a=msid" line or lines **MUST** stay the same if they are present in the current description, regardless of changes to the transceiver's direction or track. If no "a=msid" line is present in the current description, "a=msid" line(s) **MUST** be generated according to the same rules as for an initial offer.

*Each "m=" and "c=" line **MUST** be filled in with the port, relevant RTP profile, and address of the default candidate for the "m=" section, as described in [\[RFC8839\]](#), [Section 4.2.1.2](#) and clarified in [Section 5.1.2](#). If no RTP candidates have yet been gathered, default values **MUST** still be used, as described above.

*Each "a=mid" line **MUST** stay the same.

*Each "a=ice-ufrag" and "a=ice-pwd" line **MUST** stay the same, unless the ICE configuration has changed (e.g., changes to either the supported STUN/TURN servers or the ICE candidate policy) or the IceRestart option ([Section 5.2.3.1](#)) was specified. If the "m=" section is bundled into another "m=" section, it still **MUST NOT** contain any ICE credentials.

*If the "m=" section is not bundled into another "m=" section, its "a=rtcp" attribute line **MUST** be filled in with the port and address of the default RTCP candidate, as indicated in [\[RFC5761\]](#), [Section 5.1.3](#). If no RTCP candidates have yet been gathered, default values **MUST** be used, as described in [Section 5.2.1](#) above.

*If the "m=" section is not bundled into another "m=" section, for each candidate that has been gathered during the most recent gathering phase (see [Section 3.5.1](#)), an "a=candidate" line **MUST** be added, as defined in [\[RFC8839\]](#), [Section 5.1](#). If candidate gathering for the section has completed, an "a=end-of-candidates"

attribute **MUST** be added, as described in [[RFC8840](#)], [Section 8.2](#).
If the "m=" section is bundled into another "m=" section, both "a=candidate" and "a=end-of-candidates" **MUST** be omitted.

*For RtpTransceivers that are still present, the "a=rid" lines **MUST** stay the same.

*For RtpTransceivers that are still present, any "a=simulcast" line **MUST** stay the same.

If the previous offer was applied using setLocalDescription, and a corresponding answer from the remote side has been applied using setRemoteDescription, meaning the PeerConnection is in the "have-remote-pranswer" state or the "stable" state, an offer is generated based on the negotiated session descriptions by following the steps mentioned for the "have-local-offer" state above.

In addition, for each existing, non-recycled, non-rejected "m=" section in the new offer, the following adjustments are made based on the contents of the corresponding "m=" section in the current local or remote description, as appropriate:

*The "m=" line and corresponding "a=rtpmap" and "a=fmtp" lines **MUST** only include media formats that have not been excluded by the codec preferences of the associated transceiver and also **MUST** include all currently available formats. Media formats that were previously offered but are no longer available (e.g., a shared hardware codec) **MAY** be excluded.

*Unless codec preferences have been set for the associated transceiver, the media formats on the "m=" line **MUST** be generated in the same order as in the most recent answer. Any media formats that were not present in the most recent answer **MUST** be added after all existing formats.

*The RTP header extensions **MUST** only include those that are supported by the application on the associated transceiver.

*The RTCP feedback mechanisms **MUST** only include those that are supported by the application on the associated transceiver.

*The "a=rtcp" line **MUST NOT** be added if the most recent answer included an "a=rtcp-mux" line.

*The "a=rtcp-mux" line **MUST** be the same as that in the most recent answer.

*The "a=rtcp-mux-only" line **MUST NOT** be added.

*The "a=rtcp-rsize" line **MUST NOT** be added unless present in the most recent answer.

*An "a=bundle-only" line, as defined in [[RFC9143](#)], [Section 6](#), **MUST NOT** be added. Instead, JSEP implementations **MUST** simply omit parameters in the IDENTICAL and TRANSPORT categories for bundled "m=" sections, as described in [[RFC9143](#)], [Section 7.1.3](#).

*Note that if media "m=" sections are bundled into a data "m=" section, then certain TRANSPORT and IDENTICAL attributes may appear in the data "m=" section even if they would otherwise only be appropriate for a media "m=" section (e.g., "a=rtcp-mux"). This cannot happen in initial offers because in the initial offer JSEP implementations always list media "m=" sections (if any) before the data "m=" section (if any), and at least one of those media "m=" sections will not have the "a=bundle-only" attribute. Therefore, in initial offers, any "a=bundle-only" "m=" sections will be bundled into a preceding non-bundle-only media "m=" section.

The "a=group:BUNDLE" attribute **MUST** include the MID identifiers specified in the bundle group in the most recent answer, minus any "m=" sections that have been marked as rejected, plus any newly added or re-enabled "m=" sections. In other words, the bundle attribute **MUST** contain all "m=" sections that were previously bundled, as long as they are still alive, as well as any new "m=" sections.

Note that if bundling has been negotiated, unbundling is no longer possible, and media sections will not be marked as bundle-only. This is by design, but could cause issues in the rare case of sending a subsequent offer as an initial offer to a non-bundle-aware endpoint via Third Party Call Control (3PCC), as discussed in [[RFC9143](#)], [Section 7.6](#).

"a=group:LS" attributes are generated in the same way as for initial offers, with the additional stipulation that any lip sync groups that were present in the most recent answer **MUST** continue to exist and **MUST** contain any previously existing MID identifiers, as long as the identified "m=" sections still exist and are not rejected, and the group still contains at least two MID identifiers. This ensures that any synchronized "recvonly" "m=" sections continue to be synchronized in the new offer.

5.2.3. Options Handling

The createOffer method takes as a parameter an RTCOfferOptions object. Special processing is performed when generating an SDP description if the following options are present.

5.2.3.1. IceRestart

If the IceRestart option is specified, with a value of "true", the offer **MUST** indicate an ICE restart by generating new ICE ufrag and pwd attributes, as specified in [\[RFC8839\]](#), [Section 4.4.3.1.1](#). If this option is specified on an initial offer, it has no effect (since a new ICE ufrag and pwd are already generated). Similarly, if the ICE configuration has changed, this option has no effect, since new ufrag and pwd attributes will be generated automatically. This option is primarily useful for reestablishing connectivity in cases where failures are detected by the application.

5.2.3.2. VoiceActivityDetection

Silence suppression, also known as discontinuous transmission ("DTX"), can reduce the bandwidth used for audio by switching to a special encoding when voice activity is not detected, at the cost of some fidelity.

If the "VoiceActivityDetection" option is specified, with a value of "true", the offer **MUST** indicate support for silence suppression in the audio it receives by including comfort noise ("CN") codecs for each offered audio codec, as specified in [\[RFC3389\]](#), [Section 5.1](#), except for codecs that have their own internal silence suppression support. For codecs that have their own internal silence suppression support, the appropriate fmp parameters for that codec **MUST** be specified to indicate that silence suppression for received audio is desired. For example, when using the Opus codec [\[RFC6716\]](#), the "usedtx=1" parameter, specified in [\[RFC7587\]](#), would be used in the offer.

If the "VoiceActivityDetection" option is specified, with a value of "false", the JSEP implementation **MUST NOT** emit "CN" codecs. For codecs that have their own internal silence suppression support, the appropriate fmp parameters for that codec **MUST** be specified to indicate that silence suppression for received audio is not desired. For example, when using the Opus codec, the "usedtx=0" parameter would be specified in the offer. In addition, the implementation **MUST NOT** use silence suppression for media it generates, regardless of whether the "CN" codecs or related fmp parameters appear in the peer's description. The impact of these rules is that silence suppression in JSEP depends on mutual agreement of both sides, which ensures consistent handling regardless of which codec is used.

The "VoiceActivityDetection" option does not have any impact on the setting of the "vad" value in the signaling of the client-to-mixer audio level header extension described in [\[RFC6464\]](#), [Section 4](#).

5.3. Generating an Answer

When `createAnswer` is called, a new SDP description **MUST** be created that is compatible with the supplied remote description as well as the requirements specified in [\[RFC8834\]](#). The exact details of this process are explained below.

5.3.1. Initial Answers

When `createAnswer` is called for the first time after a remote description has been provided, the result is known as the initial answer. If no remote description has been installed, an answer cannot be generated, and an error **MUST** be returned.

Note that the remote description SDP may not have been created by a JSEP endpoint and may not conform to all the requirements listed in [Section 5.2](#). For many cases, this is not a problem. However, if any mandatory SDP attributes are missing or functionality listed as mandatory-to-use above is not present, this **MUST** be treated as an error and **MUST** cause the affected "m=" sections to be marked as rejected.

The first step in generating an initial answer is to generate session-level attributes. The process here is identical to that indicated in [Section 5.2.1](#) above, except that the "a=ice-options" line, with the "trickle" option as specified in [\[RFC8840\]](#), [Section 4.1.3](#) and the "ice2" option as specified in [\[RFC8445\]](#), [Section 10](#), is only included if such an option was present in the offer.

The next step is to generate session-level lip sync groups, as defined in [\[RFC5888\]](#), [Section 7](#). For each group of type "LS" present in the offer, select the local `RtpTransceivers` that are referenced by the MID values in the specified group, and determine which of them either reference a common local `MediaStream` (specified in the calls to `addTrack/addTransceiver` used to create them) or have no `MediaStream` to reference because they were not created by `addTrack/addTransceiver`. If at least two such `RtpTransceivers` exist, a group of type "LS" with the MID values of these `RtpTransceivers` **MUST** be added. Otherwise, the offered "LS" group **MUST** be ignored and no corresponding group generated in the answer.

As a simple example, consider the following offer of a single audio and single video track contained in the same `MediaStream`. SDP lines not relevant to this example have been removed for clarity. As explained in [Section 5.2](#), a group of type "LS" has been added that references each track's `RtpTransceiver`.

```
a=group:LS a1 v1
m=audio 10000 UDP/TLS/RTP/SAVPF 0
a=mid:a1
a=msid:ms1
m=video 10001 UDP/TLS/RTP/SAVPF 96
a=mid:v1
a=msid:ms1
```

If the answerer uses a single MediaStream when it adds its tracks, both of its transceivers will reference this stream, and so the subsequent answer will contain a "LS" group identical to that in the offer, as shown below:

```
a=group:LS a1 v1
m=audio 20000 UDP/TLS/RTP/SAVPF 0
a=mid:a1
a=msid:ms2
m=video 20001 UDP/TLS/RTP/SAVPF 96
a=mid:v1
a=msid:ms2
```

However, if the answerer groups its tracks into separate MediaStreams, its transceivers will reference different streams, and so the subsequent answer will not contain a "LS" group.

```
m=audio 20000 UDP/TLS/RTP/SAVPF 0
a=mid:a1
a=msid:ms2a
m=video 20001 UDP/TLS/RTP/SAVPF 96
a=mid:v1
a=msid:ms2b
```

Finally, if the answerer does not add any tracks, its transceivers will not reference any MediaStreams, causing the preferences of the offerer to be maintained, and so the subsequent answer will contain an identical "LS" group.

```
a=group:LS a1 v1
m=audio 20000 UDP/TLS/RTP/SAVPF 0
a=mid:a1
a=recvonly
m=video 20001 UDP/TLS/RTP/SAVPF 96
a=mid:v1
a=recvonly
```

The example in [Section 7.2](#) shows a more involved case of "LS" group generation.

The next step is to generate a "m=" section for each "m=" section that is present in the remote offer, as specified in [\[RFC3264\]](#),

[Section 6](#). For the purposes of this discussion, any session-level attributes in the offer that are also valid as media-level attributes are considered to be present in each "m=" section. Each offered "m=" section will have an associated RtpTransceiver, as described in [Section 5.10](#). If there are more RtpTransceivers than there are "m=" sections, the unmatched RtpTransceivers will need to be associated in a subsequent offer.

For each offered "m=" section, if any of the following conditions are true, the corresponding "m=" section in the answer **MUST** be marked as rejected by setting the <port> in the "m=" line to zero, as indicated in [[RFC3264](#)], [Section 6](#), and further processing for this "m=" section can be skipped:

- *The associated RtpTransceiver has been stopped.
- *There is no offered media format that is both supported and, if applicable, allowed by codec preferences.
- *The bundle policy is "must-bundle", and this is not the first "m=" section or in the same bundle group as the first "m=" section.
- *The bundle policy is "balanced", and this is not the first "m=" section for this media type or in the same bundle group as the first "m=" section for this media type.
- *This "m=" section is in a bundle group, and the group's offerer tagged "m=" section is being rejected due to one of the above reasons. This requires all "m=" sections in the bundle group to be rejected, as specified in [[RFC9143](#)], [Section 7.3.3](#).

Otherwise, each "m=" section in the answer **MUST** then be generated as specified in [[RFC3264](#)], [Section 6.1](#). For the "m=" line itself, the following rules **MUST** be followed:

- *The <port> value would normally be set to the port of the default ICE candidate for this "m=" section, but given that no candidates are available yet, the default <port> value of 9 (Discard) **MUST** be used, as indicated in [[RFC8840](#)], [Section 4.1.1](#).
- *The <proto> field **MUST** be set to exactly match the <proto> field for the corresponding "m=" line in the offer.
- *If codec preferences have been set for the associated transceiver, media formats **MUST** be generated in the corresponding order, regardless of what was offered, and **MUST** exclude any codecs not present in the codec preferences.
- *Otherwise, the media formats on the "m=" line **MUST** be generated in the same order as those offered in the current remote description,

excluding any currently unsupported formats. Any currently available media formats that are not present in the current remote description **MUST** be added after all existing formats.

*In either case, the media formats in the answer **MUST** include at least one format that is present in the offer but **MAY** include formats that are locally supported but not present in the offer, as mentioned in [[RFC3264](#)], [Section 6.1](#). If no common format exists, the "m=" section is rejected as described above.

The "m=" line **MUST** be followed immediately by a "c=" line, as specified in [[RFC4566](#)], [Section 5.7](#). Again, as no candidates are available yet, the "c=" line **MUST** contain the default value "IN IP4 0.0.0.0", as defined in [[RFC8840](#)], [Section 4.1.3](#).

If the offer supports bundle, all "m=" sections to be bundled **MUST** use the same ICE credentials and candidates; all "m=" sections not being bundled **MUST** use unique ICE credentials and candidates. Each "m=" section **MUST** contain the following attributes (which are of attribute types other than IDENTICAL or TRANSPORT):

*If and only if present in the offer, an "a=mid" line, as specified in [[RFC5888](#)], [Section 9.1](#). The MID value **MUST** match that specified in the offer.

*A direction attribute, determined by applying the rules regarding the offered direction specified in [[RFC3264](#)], [Section 6.1](#), and then intersecting with the direction of the associated RtpTransceiver. For example, in the case where an "m=" section is offered as "sendonly" and the local transceiver is set to "sendrecv", the result in the answer is a "recvonly" direction.

*For each media format on the "m=" line, "a=rtpmap" and "a=fmtp" lines, as specified in [[RFC4566](#)], [Section 6](#) and [[RFC3264](#)], [Section 6.1](#).

*If "rtx" is present in the offer, for each primary codec where RTP retransmission should be used, a corresponding "a=rtpmap" line indicating "rtx" with the clock rate of the primary codec and an "a=fmtp" line that references the payload type of the primary codec, as specified in [[RFC4588](#)], [Section 8.1](#).

*For each FEC mechanism supported by the application, "a=rtpmap" and "a=fmtp" lines, as specified in [[RFC4566](#)], [Section 6](#). The FEC mechanisms that **MUST** be supported are specified in [[RFC8854](#)], [Section 7](#), and specific usage for each media type is outlined in [Sections 4](#) and [5](#).

*If this "m=" section is for media with configurable durations of media per packet, e.g., audio, an "a=maxptime" line, as described in [Section 5.2](#).

*If this "m=" section is for video media and there are known limitations on the size of images that can be decoded, an "a=imageattr" line, as specified in [Section 3.6](#).

*For each RTP header extension supported by the application and present in the offer, an "a=extmap" line, as specified in [[RFC5285](#)], [Section 5](#). The list of header extensions that **SHOULD/MUST** be supported is specified in [[RFC8834](#)], [Section 5.2](#). Any header extensions that require encryption **MUST** be specified as indicated in [[RFC6904](#)], [Section 4](#).

*For each RTCP feedback mechanism supported by the application and present in the offer, an "a=rtcp-fb" line, as specified in [[RFC4585](#)], [Section 4.2](#). The list of RTCP feedback mechanisms that **SHOULD/MUST** be supported is specified in [[RFC8834](#)], [Section 5.1](#).

*If the RtpTransceiver has a sendrecv or sendonly direction:

-For each MediaStream that was associated with the transceiver when it was created via addTrack or addTransceiver, an "a=msid" line, as specified in [[RFC8830](#)], [Section 2](#), but omitting the "appdata" field.

Each "m=" section that is not bundled into another "m=" section **MUST** contain the following attributes (which are of category IDENTICAL or TRANSPORT):

*"a=ice-ufrag" and "a=ice-pwd" lines, as specified in [[RFC8839](#)], [Section 5.4](#).

*For each desired digest algorithm, one or more "a=fingerprint" lines for each of the endpoint's certificates, as specified in [[RFC8122](#)], [Section 5](#).

*An "a=setup" line, as specified in [[RFC4145](#)], [Section 4](#) and clarified for use in DTLS-SRTP scenarios in [[RFC5763](#)], [Section 5](#). The role value in the answer **MUST** be "active" or "passive". When the offer contains the "actpass" value, as will always be the case with JSEP endpoints, the answerer **SHOULD** use the "active" role. Offers from non-JSEP endpoints **MAY** send other values for "a=setup", in which case the answer **MUST** use a value consistent with the value in the offer.

*An "a=tls-id" line, as specified in [[RFC8842](#)], [Section 5.3](#).

*If present in the offer, an "a=rtcp-mux" line, as specified in [[RFC5761](#)], [Section 5.1.3](#). Otherwise, an "a=rtcp" line, as specified in [[RFC3605](#)], [Section 2.1](#), containing the default value "9 IN IP4 0.0.0.0" (because no candidates have yet been gathered).

*If present in the offer, an "a=rtcp-rsize" line, as specified in [[RFC5506](#)], [Section 5](#).

If a data channel "m=" section has been offered, an "m=" section **MUST** also be generated for data. The <media> field **MUST** be set to "application", and the <proto> and <fmt> fields **MUST** be set to exactly match the fields in the offer.

Within the data "m=" section, an "a=mid" line **MUST** be generated and included as described above, along with an "a=sctp-port" line referencing the SCTP port number, as defined in [[RFC8841](#)], [Section 5.1](#); and, if appropriate, an "a=max-message-size" line, as defined in [[RFC8841](#)], [Section 6.1](#).

As discussed above, the following attributes of category IDENTICAL or TRANSPORT are included only if the data "m=" section is not bundled into another "m=" section:

*"a=ice-ufrag"

*"a=ice-pwd"

*"a=fingerprint"

*"a=setup"

*"a=tls-id"

Note that if media "m=" sections are bundled into a data "m=" section, then certain TRANSPORT and IDENTICAL attributes may also appear in the data "m=" section even if they would otherwise only be appropriate for a media "m=" section (e.g., "a=rtcp-mux").

If "a=group" attributes with semantics of "BUNDLE" are offered, corresponding session-level "a=group" attributes **MUST** be added as specified in [[RFC5888](#)]. These attributes **MUST** have semantics "BUNDLE" and **MUST** include all mid identifiers from the offered bundle groups that have not been rejected. Note that regardless of the presence of "a=bundle-only" in the offer, all "m=" sections in the answer **MUST NOT** have an "a=bundle-only" line.

Attributes that are common between all "m=" sections **MAY** be moved to the session level if explicitly defined to be valid at the session level.

The attributes prohibited in the creation of offers are also prohibited in the creation of answers.

5.3.2. Subsequent Answers

When `createAnswer` is called a second (or later) time or is called after a local description has already been installed, the processing is somewhat different than for an initial answer.

If the previous answer was not applied using `setLocalDescription`, meaning the `PeerConnection` is still in the "have-remote-offer" state, the steps for generating an initial answer **MUST** be followed, subject to the following restriction:

- *The fields of the "o=" line **MUST** stay the same except for the <session-version> field, which **MUST** increment if the session description changes in any way from the previously generated answer.

If any session description was previously supplied to `setLocalDescription`, an answer is generated by following the steps in the "have-remote-offer" state above, along with these exceptions:

- *The "s=" and "t=" lines **MUST** stay the same.

- *Each "m=" and "c=" line **MUST** be filled in with the port and address of the default candidate for the "m=" section, as described in [[RFC8839](#)], [Section 4.2.1.2](#). Note that in certain cases, the "m=" line protocol may not match that of the default candidate, because the "m=" line protocol value **MUST** match what was supplied in the offer, as described above.

- *Each "a=ice-ufrag" and "a=ice-pwd" line **MUST** stay the same, unless the "m=" section is restarting, in which case new ICE credentials **MUST** be created as specified in [[RFC8839](#)], [Section 4.4.1.1.1](#). If the "m=" section is bundled into another "m=" section, it still **MUST NOT** contain any ICE credentials.

- *Each "a=tls-id" line **MUST** stay the same, unless the offerer's "a=tls-id" line changed, in which case a new tls-id value **MUST** be created, as described in [[RFC8842](#)], [Section 5.2](#).

- *Each "a=setup" line **MUST** use an "active" or "passive" role value consistent with the existing DTLS association, if the association is being continued by the offerer.

- *RTCP multiplexing **MUST** be used, and an "a=rtcp-mux" line inserted if and only if the "m=" section previously used RTCP multiplexing.

*If the "m=" section is not bundled into another "m=" section and RTCP multiplexing is not active, an "a=rtcp" attribute line **MUST** be filled in with the port and address of the default RTCP candidate. If no RTCP candidates have yet been gathered, default values **MUST** be used, as described in [Section 5.3.1](#) above.

*If the "m=" section is not bundled into another "m=" section, for each candidate that has been gathered during the most recent gathering phase (see [Section 3.5.1](#)), an "a=candidate" line **MUST** be added, as defined in [[RFC8839](#)], [Section 5.1](#). If candidate gathering for the section has completed, an "a=end-of-candidates" attribute **MUST** be added, as described in [[RFC8840](#)], [Section 8.2](#). If the "m=" section is bundled into another "m=" section, both "a=candidate" and "a=end-of-candidates" **MUST** be omitted.

*For RtpTransceivers that are not stopped, the "a=msid" line(s) **MUST** stay the same, regardless of changes to the transceiver's direction or track. If no "a=msid" line is present in the current description, "a=msid" line(s) **MUST** be generated according to the same rules as for an initial answer.

5.3.3. Options Handling

The createAnswer method takes as a parameter an RTCAnswerOptions object. The set of parameters for RTCAnswerOptions is different than those supported in RTCOfferOptions; the IceRestart option is unnecessary, as ICE credentials will automatically be changed for all "m=" sections where the offerer chose to perform ICE restart.

The following options are supported in RTCAnswerOptions.

5.3.3.1. VoiceActivityDetection

Silence suppression in the answer is handled as described in [Section 5.2.3.2](#), with one exception: if support for silence suppression was not indicated in the offer, the VoiceActivityDetection parameter has no effect, and the answer **MUST** be generated as if VoiceActivityDetection was set to "false". This is done on a per-codec basis (e.g., if the offerer somehow offered support for CN but set "usedtx=0" for Opus, setting VoiceActivityDetection to "true" would result in an answer with CN codecs and "usedtx=0"). The impact of this rule is that an answerer will not try to use silence suppression with any endpoint that does not offer it, making silence suppression support bilateral even with non-JSEP endpoints.

5.4. Modifying an Offer or Answer

The SDP returned from createOffer or createAnswer **MUST NOT** be changed before passing it to setLocalDescription. If precise control over the

SDP is needed, the aforementioned createOffer/createAnswer options or RtpTransceiver APIs **MUST** be used.

After calling setLocalDescription with an offer or answer, the application **MAY** modify the SDP to reduce its capabilities before sending it to the far side, as long as it follows the rules above that define a valid JSEP offer or answer. Likewise, an application that has received an offer or answer from a peer **MAY** modify the received SDP, subject to the same constraints, before calling setRemoteDescription.

As always, the application is solely responsible for what it sends to the other party, and all incoming SDP will be processed by the JSEP implementation to the extent of its capabilities. It is an error to assume that all SDP is well formed; however, one should be able to assume that any implementation of this specification will be able to process, as a remote offer or answer, unmodified SDP coming from any other implementation of this specification.

5.5. Processing a Local Description

When a SessionDescription is supplied to setLocalDescription, the following steps **MUST** be performed:

- *If the description is of type "rollback", follow the processing defined in [Section 5.7](#) and skip the processing described in the rest of this section.

- *Otherwise, the type of the SessionDescription is checked against the current state of the PeerConnection:

 - If the type is "offer", the PeerConnection state **MUST** be either "stable" or "have-local-offer".

 - If the type is "pranswer" or "answer", the PeerConnection state **MUST** be either "have-remote-offer" or "have-local-pranswer".

- *If the type is not correct for the current state, processing **MUST** stop and an error **MUST** be returned.

- *The SessionDescription is then checked to ensure that its contents are identical to those generated in the last call to createOffer/createAnswer, and thus have not been altered, as discussed in [Section 5.4](#); otherwise, processing **MUST** stop and an error **MUST** be returned.

- *Next, the SessionDescription is parsed into a data structure, as described in [Section 5.8](#) below.

*Finally, the parsed SessionDescription is applied as described in [Section 5.9](#) below.

5.6. Processing a Remote Description

When a SessionDescription is supplied to setRemoteDescription, the following steps **MUST** be performed:

*If the description is of type "rollback", follow the processing defined in [Section 5.7](#) and skip the processing described in the rest of this section.

*Otherwise, the type of the SessionDescription is checked against the current state of the PeerConnection:

-If the type is "offer", the PeerConnection state **MUST** be either "stable" or "have-remote-offer".

-If the type is "pranswer" or "answer", the PeerConnection state **MUST** be either "have-local-offer" or "have-remote-pranswer".

*If the type is not correct for the current state, processing **MUST** stop and an error **MUST** be returned.

*Next, the SessionDescription is parsed into a data structure, as described in [Section 5.8](#) below. If parsing fails for any reason, processing **MUST** stop and an error **MUST** be returned.

*Finally, the parsed SessionDescription is applied as described in [Section 5.10](#) below.

5.7. Processing a Rollback

A rollback may be performed if the PeerConnection is in any state except for "stable". This means that both offers and provisional answers can be rolled back. Rollback can only be used to cancel proposed changes; there is no support for rolling back from a "stable" state to a previous "stable" state. If a rollback is attempted in the "stable" state, processing **MUST** stop and an error **MUST** be returned. Note that this implies that once the answerer has performed setLocalDescription with its answer, this cannot be rolled back.

The effect of rollback **MUST** be the same regardless of whether setLocalDescription or setRemoteDescription is called.

In order to process rollback, a JSEP implementation abandons the current offer/answer transaction, sets the signaling state to "stable", and sets the pending local and/or remote description (see Sections [4.1.14](#) and [4.1.16](#)) to "null". Any resources or candidates

that were allocated by the abandoned local description are discarded; any media that is received is processed according to the previous local and remote descriptions.

A rollback disassociates any RtpTransceivers that were associated with "m=" sections by the application of the rolled-back session description (see Sections [5.10](#) and [5.9](#)). This means that some RtpTransceivers that were previously associated will no longer be associated with any "m=" section; in such cases, the value of the RtpTransceiver's mid property **MUST** be set to "null", and the mapping between the transceiver and its "m=" section index **MUST** be discarded. RtpTransceivers that were created by applying a remote offer that was subsequently rolled back **MUST** be stopped and removed from the PeerConnection. However, an RtpTransceiver **MUST NOT** be removed if a track was attached to the RtpTransceiver via the addTrack method. This is so that an application may call addTrack, then call setRemoteDescription with an offer, then roll back that offer, then call createOffer and have an "m=" section for the added track appear in the generated offer.

5.8. Parsing a Session Description

The SDP contained in the session description object consists of a sequence of text lines, each containing a key-value expression, as described in [[RFC4566](#)], [Section 5](#). The SDP is read, line by line, and converted to a data structure that contains the deserialized information. However, SDP allows many types of lines, not all of which are relevant to JSEP applications. For each line, the implementation will first ensure that it is syntactically correct according to its defining ABNF, check that it conforms to the semantics used in [[RFC4566](#)] and [[RFC3264](#)], and then either parse and store or discard the provided value, as described below.

If any line is not well formed or cannot be parsed as described, the parser **MUST** stop with an error and reject the session description, even if the value is to be discarded. This ensures that implementations do not accidentally misinterpret ambiguous SDP.

5.8.1. Session-Level Parsing

First, the session-level lines are checked and parsed. These lines **MUST** occur in a specific order, and with a specific syntax, as defined in [[RFC4566](#)], [Section 5](#). Note that while the specific line types (e.g., "v=", "c=") **MUST** occur in the defined order, lines of the same type (typically "a=") can occur in any order.

The following non-attribute lines are not meaningful in the JSEP context and **MAY** be discarded once they have been checked.

*The "c=" line **MUST** be checked for syntax, but its value is only used for ICE mismatch detection, as defined in [[RFC8445](#)], [Section 5.4](#). Note that JSEP implementations should never encounter this condition because ICE is required for WebRTC.

*The "i=", "u=", "e=", "p=", "t=", "r=", "z=", and "k=" lines **MUST** be checked for syntax, but their values are not otherwise used.

The remaining non-attribute lines are processed as follows:

*The "v=" line **MUST** have a version of 0, as specified in [[RFC4566](#)], [Section 5.1](#).

*The "o=" line **MUST** be parsed as specified in [[RFC4566](#)], [Section 5.2](#).

*The "b=" line, if present, **MUST** be parsed as specified in [[RFC4566](#)], [Section 5.8](#), and the bwtype and bandwidth values stored.

Finally, the attribute lines are processed. Specific processing **MUST** be applied for the following session-level attribute ("a=") lines:

*Any "a=group" lines are parsed as specified in [[RFC5888](#)], [Section 5](#), and the group's semantics and mids are stored.

*If present, a single "a=ice-lite" line is parsed as specified in [[RFC8839](#)], [Section 5.3](#), and a value indicating the presence of ice-lite is stored.

*If present, a single "a=ice-ufrag" line is parsed as specified in [[RFC8839](#)], [Section 5.4](#), and the ufrag value is stored.

*If present, a single "a=ice-pwd" line is parsed as specified in [[RFC8839](#)], [Section 5.4](#), and the password value is stored.

*If present, a single "a=ice-options" line is parsed as specified in [[RFC8839](#)], [Section 5.6](#), and the set of specified options is stored.

*Any "a=fingerprint" lines are parsed as specified in [[RFC8122](#)], [Section 5](#), and the set of fingerprint and algorithm values is stored.

*If present, a single "a=setup" line is parsed as specified in [[RFC4145](#)], [Section 4](#), and the setup value is stored.

*If present, a single "a=tls-id" line is parsed as specified in [RFC8842], [Section 5](#), and the attribute value is stored.

*Any "a=identity" lines are parsed and the identity values stored for subsequent verification, as specified in [RFC8827], [Section 5](#).

*Any "a=extmap" lines are parsed as specified in [RFC5285], [Section 5](#), and their values are stored.

Other attributes that are not relevant to JSEP may also be present, and implementations **SHOULD** process any that they recognize. As required by [RFC4566], [Section 5.13](#), unknown attribute lines **MUST** be ignored.

Once all the session-level lines have been parsed, processing continues with the lines in "m=" sections.

5.8.2. Media Section Parsing

Like the session-level lines, the media section lines **MUST** occur in the specific order and with the specific syntax defined in [RFC4566], [Section 5](#).

The "m=" line itself **MUST** be parsed as described in [RFC4566], [Section 5.14](#), and the <media>, <port>, <proto>, and <fmt> values stored.

Following the "m=" line, specific processing **MUST** be applied for the following non-attribute lines:

*As with the "c=" line at the session level, the "c=" line **MUST** be parsed according to [RFC4566], [Section 5.7](#), but its value is not used.

*The "b=" line, if present, **MUST** be parsed as specified in [RFC4566], [Section 5.8](#), and the bwtype and bandwidth values stored.

Specific processing **MUST** also be applied for the following attribute lines:

*If present, a single "a=ice-ufrag" line is parsed as specified in [RFC8839], [Section 5.4](#), and the ufrag value is stored.

*If present, a single "a=ice-pwd" line is parsed as specified in [RFC8839], [Section 5.4](#), and the password value is stored.

*If present, a single "a=ice-options" line is parsed as specified in [RFC8839], [Section 5.6](#), and the set of specified options is stored.

*Any "a=candidate" attributes **MUST** be parsed as specified in [[RFC8839](#)], [Section 5.1](#), and their values stored.

*Any "a=remote-candidates" attributes **MUST** be parsed as specified in [[RFC8839](#)], [Section 5.2](#), but their values are ignored.

*If present, a single "a=end-of-candidates" attribute **MUST** be parsed as specified in [[RFC8840](#)], [Section 8.1](#), and its presence or absence flagged and stored.

*Any "a=fingerprint" lines are parsed as specified in [[RFC8122](#)], [Section 5](#), and the set of fingerprint and algorithm values is stored.

If the "m=" <proto> value indicates use of RTP, as described in [Section 5.1.2](#) above, the following attribute lines **MUST** be processed:

*The "m=" <fmt> value **MUST** be parsed as specified in [[RFC4566](#)], [Section 5.14](#), and the individual values stored.

*Any "a=rtptime" or "a=fmtp" lines **MUST** be parsed as specified in [[RFC4566](#)], [Section 6](#), and their values stored.

*If present, a single "a=ptime" line **MUST** be parsed as described in [[RFC4566](#)], [Section 6](#), and its value stored.

*If present, a single "a=maxptime" line **MUST** be parsed as described in [[RFC4566](#)], [Section 6](#), and its value stored.

*If present, a single direction attribute line (e.g., "a=sendrecv") **MUST** be parsed as described in [[RFC4566](#)], [Section 6](#), and its value stored.

*Any "a=ssrc" attributes **MUST** be parsed as specified in [[RFC5576](#)], [Section 4.1](#), and their values stored.

*Any "a=extmap" attributes **MUST** be parsed as specified in [[RFC5285](#)], [Section 5](#), and their values stored.

*Any "a=rtcp-fb" attributes **MUST** be parsed as specified in [[RFC4585](#)], [Section 4.2](#), and their values stored.

*If present, a single "a=rtcp-mux" attribute **MUST** be parsed as specified in [[RFC5761](#)], [Section 5.1.3](#), and its presence or absence flagged and stored.

*If present, a single "a=rtcp-mux-only" attribute **MUST** be parsed as specified in [[RFC8858](#)], [Section 3](#), and its presence or absence flagged and stored.

*If present, a single "a=rtcp-rsize" attribute **MUST** be parsed as specified in [[RFC5506](#)], [Section 5](#), and its presence or absence flagged and stored.

*If present, a single "a=rtcp" attribute **MUST** be parsed as specified in [[RFC3605](#)], [Section 2.1](#), but its value is ignored, as this information is superfluous when using ICE.

*If present, "a=msid" attributes **MUST** be parsed as specified in [[RFC8830](#)], [Section 3.2](#), and their values stored, ignoring any "appdata" field. If no "a=msid" attributes are present, a random msid-id value is generated for a "default" MediaStream for the session, if not already present, and this value is stored.

*Any "a=imageattr" attributes **MUST** be parsed as specified in [[RFC6236](#)], [Section 3](#), and their values stored.

*Any "a=rid" lines **MUST** be parsed as specified in [[RFC8851](#)], [Section 10](#), and their values stored.

*If present, a single "a=simulcast" line **MUST** be parsed as specified in [[RFC8853](#)], and its values stored.

Otherwise, if the "m=" <proto> value indicates use of SCTP, the following attribute lines **MUST** be processed:

*The "m=" <fmt> value **MUST** be parsed as specified in [[RFC8841](#)], [Section 4.3](#), and the application protocol value stored.

*An "a=sctp-port" attribute **MUST** be present, and it **MUST** be parsed as specified in [[RFC8841](#)], [Section 5.2](#), and the value stored.

*If present, a single "a=max-message-size" attribute **MUST** be parsed as specified in [[RFC8841](#)], [Section 6](#), and the value stored. Otherwise, use the specified default.

Other attributes that are not relevant to JSEP may also be present, and implementations **SHOULD** process any that they recognize. As required by [[RFC4566](#)], [Section 5.13](#), unknown attribute lines **MUST** be ignored.

5.8.3. Semantics Verification

Assuming that parsing completes successfully, the parsed description is then evaluated to ensure internal consistency as well as proper support for mandatory features. Specifically, the following checks are performed:

*For each "m=" section, valid values for each of the mandatory-to-use features enumerated in [Section 5.1.1](#) **MUST** be present. These

values **MAY** be either present at the media level or inherited from the session level.

-ICE ufrag and password values, which **MUST** comply with the size limits specified in [[RFC8839](#)], [Section 5.4](#).

-A tls-id value, which **MUST** be set according to [[RFC8842](#)], [Section 5](#). If this is a re-offer or a response to a re-offer and the tls-id value is different from that presently in use, the DTLS connection is not being continued and the remote description **MUST** be part of an ICE restart, together with new ufrag and password values.

-A DTLS setup value, which **MUST** be set according to the rules specified in [[RFC5763](#)], [Section 5](#) and **MUST** be consistent with the selected role of the current DTLS connection, if one exists and is being continued.

-DTLS fingerprint values, where at least one fingerprint **MUST** be present.

*All rid-ids referenced in an "a=simulcast" line **MUST** exist as "a=rid" lines.

*Each "m=" section is also checked to ensure that prohibited features are not used.

*If the RTP/RTCP multiplexing policy is "require", each "m=" section **MUST** contain an "a=rtcp-mux" attribute. If an "m=" section contains an "a=rtcp-mux-only" attribute, that section **MUST** also contain an "a=rtcp-mux" attribute.

*If an "m=" section was present in the previous answer, the state of RTP/RTCP multiplexing **MUST** match what was previously negotiated.

If this session description is of type "pranswer" or "answer", the following additional checks are applied:

*The session description **MUST** follow the rules defined in [[RFC3264](#)], [Section 6](#), including the requirement that the number of "m=" sections **MUST** exactly match the number of "m=" sections in the associated offer.

*For each "m=" section, the media type and protocol values **MUST** exactly match the media type and protocol values in the corresponding "m=" section in the associated offer.

If any of the preceding checks failed, processing **MUST** stop and an error **MUST** be returned.

5.9. Applying a Local Description

The following steps are performed at the media engine level to apply a local description. If an error is returned, the session **MUST** be restored to the state it was in before performing these steps.

First, "m=" sections are processed. For each "m=" section, the following steps **MUST** be performed; if any parameters are out of bounds or cannot be applied, processing **MUST** stop and an error **MUST** be returned.

*If this "m=" section is new, begin gathering candidates for it, as defined in [\[RFC8445\]](#), [Section 5.1.1](#), unless it is definitively being bundled (either (1) this is an offer and the "m=" section is marked as bundle-only or (2) it is an answer and the "m=" section is bundled into another "m=" section).

*Or, if the ICE ufrag and password values have changed, trigger the ICE agent to start an ICE restart as described in [\[RFC8445\]](#), [Section 9](#), and begin gathering new candidates for the "m=" section. If this description is an answer, also start checks on that media section.

*If the "m=" section <proto> value indicates use of RTP:

- If there is no RtpTransceiver associated with this "m=" section, find one and associate it with this "m=" section according to the following steps. Note that this situation will only occur when applying an offer.

- oFind the RtpTransceiver that corresponds to this "m=" section, using the mapping between transceivers and "m=" section indices established when creating the offer.

- oSet the value of this RtpTransceiver's mid property to the MID of the "m=" section.

- If RTCP mux is indicated, prepare to demux RTP and RTCP from the RTP ICE component, as specified in [\[RFC5761\]](#), [Section 5.1.3](#).

- For each specified RTP header extension, establish a mapping between the extension ID and URI, as described in [\[RFC5285\]](#), [Section 6](#).

- If the MID header extension is supported, prepare to demux RTP streams intended for this "m=" section based on the MID header extension, as described in [\[RFC9143\]](#), [Section 15](#).

- For each specified media format, establish a mapping between the payload type and the actual media format, as described in [RFC3264], [Section 6.1](#). In addition, prepare to demux RTP streams intended for this "m=" section based on the media formats supported by this "m=" section, as described in [RFC9143], [Section 9.2](#).
- For each specified "rtx" media format, establish a mapping between the RTX payload type and its associated primary payload type, as described in Sections [8.6](#) and [8.7](#) of [RFC4588].
- If the direction attribute is of type "sendrecv" or "recvonly", enable receipt and decoding of media.

Finally, if this description is of type "pranswer" or "answer", follow the processing defined in [Section 5.11](#) below.

5.10. Applying a Remote Description

The following steps are performed to apply a remote description. If an error is returned, the session **MUST** be restored to the state it was in before performing these steps.

If the answer contains any "a=ice-options" attributes where "trickle" is listed as an attribute, update the PeerConnection canTrickleIceCandidates property to be "true". Otherwise, set this property to "false".

The following steps **MUST** be performed for attributes at the session level; if any parameters are out of bounds or cannot be applied, processing **MUST** stop and an error **MUST** be returned.

*For any specified "CT" bandwidth value, set this value as the limit for the maximum total bitrate for all "m=" sections, as specified in [RFC4566], [Section 5.8](#). Within this overall limit, the implementation can dynamically decide how to best allocate the available bandwidth between "m=" sections, respecting any specific limits that have been specified for individual "m=" sections.

*For any specified "RR" or "RS" bandwidth values, handle as specified in [RFC3556], [Section 2](#).

*Any "AS" bandwidth value ([RFC4566], [Section 5.8](#)) **MUST** be ignored, as the meaning of this construct at the session level is not well defined.

For each "m=" section, the following steps **MUST** be performed; if any parameters are out of bounds or cannot be applied, processing **MUST** stop and an error **MUST** be returned.

*If the ICE ufrag or password changed from the previous remote description:

- If the description is of type "offer", the implementation **MUST** note that an ICE restart is needed, as described in [[RFC8839](#)], [Section 4.4.1.1.1](#).

- If the description is of type "answer" or "pranswer", then check to see if the current local description is an ICE restart, and if not, generate an error. If the PeerConnection state is "have-remote-pranswer" and the ICE ufrag or password changed from the previous provisional answer, then signal the ICE agent to discard any previous ICE checklist state for the "m=" section. Finally, signal the ICE agent to begin checks.

*If the current local description indicates an ICE restart but neither the ICE ufrag nor the password has changed from the previous remote description (as prescribed by [[RFC8445](#)], [Section 9](#)), generate an error.

*Configure the ICE components associated with this media section to use the supplied ICE remote ufrag and password for their connectivity checks.

*Pair any supplied ICE candidates with any gathered local candidates, as described in [[RFC8445](#)], [Section 6.1.2](#), and start connectivity checks with the appropriate credentials.

*If an "a=end-of-candidates" attribute is present, process the end-of-candidates indication as described in [[RFC8838](#)], [Section 14](#).

*If the "m=" section <proto> value indicates use of RTP:

- If the "m=" section is being recycled (see [Section 5.2.2](#)), disassociate the currently associated RtpTransceiver by setting its mid property to "null", and discard the mapping between the transceiver and its "m=" section index.

- If the "m=" section is not associated with any RtpTransceiver (possibly because it was disassociated in the previous step), either find an RtpTransceiver or create one according to the following steps:

- oIf the "m=" section is sendrecv or recvonly, and there are RtpTransceivers of the same type that were added to the PeerConnection by addTrack and are not associated with any

"m=" section and are not stopped, find the first (according to the canonical order described in [Section 5.2.1](#)) such RtpTransceiver.

oIf no RtpTransceiver was found in the previous step, create one with a recvonly direction.

oAssociate the found or created RtpTransceiver with the "m=" section by setting the value of the RtpTransceiver's mid property to the MID of the "m=" section, and establish a mapping between the transceiver and the index of the "m=" section. If the "m=" section does not include a MID (i.e., the remote endpoint does not support the MID extension), generate a value for the RtpTransceiver mid property, following the guidance for "a=mid" mentioned in [Section 5.2.1](#).

-For each specified media format that is also supported by the local application, establish a mapping between the specified payload type and the media format, as described in [[RFC3264](#)], [Section 6.1](#). Specifically, this means that the implementation records the payload type to be used in outgoing RTP packets when sending each specified media format, as well as the relative preference for each format that is indicated in their ordering. If any indicated media format is not supported by the local application, it **MUST** be ignored.

-For each specified "rtx" media format, establish a mapping between the RTX payload type and its associated primary payload type, as described in [[RFC4588](#)], [Section 4](#). If any referenced primary payload types are not present, this **MUST** result in an error. Note that RTX payload types may refer to primary payload types that are not supported by the local media implementation, in which case the RTX payload type **MUST** also be ignored.

-For each specified fmp parameter that is supported by the local implementation, enable them on the associated media formats.

-For each specified Synchronization Source (SSRC) that is signaled in the "m=" section, prepare to demux RTP streams intended for this "m=" section using that SSRC, as described in [[RFC9143](#)], [Section 9.2](#).

-For each specified RTP header extension that is also supported by the local application, establish a mapping between the extension ID and URI, as described in [[RFC5285](#)], [Section 5](#). Specifically, this means that the implementation records the extension ID to be used in outgoing RTP packets when sending

each specified header extension. If any indicated RTP header extension is not supported by the local application, it **MUST** be ignored.

- For each specified RTCP feedback mechanism that is also supported by the local application, enable them on the associated media formats.
- For any specified "TIAS" ("Transport Independent Application Specific Maximum") bandwidth value, set this value as a constraint on the maximum RTP bitrate to be used when sending media, as specified in [[RFC3890](#)]. If a "TIAS" value is not present but an "AS" value is specified, generate a "TIAS" value using this formula:

$$\text{TIAS} = \text{AS} * 1000 * 0.95 - (50 * 40 * 8)$$

The 1000 changes the unit from kbps to bps (as required by TIAS), and the 0.95 is to allocate 5% to RTCP. An estimate of header overhead is then subtracted out, in which the 50 is based on 50 packets per second, the 40 is based on typical header size (in bytes), and the 8 converts bytes to bits. Note that "TIAS" is preferred over "AS" because it provides more accurate control of bandwidth.

- For any "RR" or "RS" bandwidth values, handle as specified in [[RFC3556](#)], [Section 2](#).
- Any specified "CT" bandwidth value **MUST** be ignored, as the meaning of this construct at the media level is not well defined.
- If the "m=" section is of type "audio":
 - oFor each specified "CN" media format, configure silence suppression for all supported media formats with the same clock rate, as described in [[RFC3389](#)], [Section 5](#), except for formats that have their own internal silence suppression mechanisms. Silence suppression for such formats (e.g., Opus) is controlled via fmp parameters, as discussed in [Section 5.2.3.2](#).
 - oFor each specified "telephone-event" media format, enable dual-tone multifrequency (DTMF) transmission for all supported media formats with the same clock rate, as described in [[RFC4733](#)], [Section 2.5.1.2](#). If there are any supported media formats that do not have a corresponding telephone-event format, disable DTMF transmission for those formats.

oFor any specified "ptime" value, configure the available media formats to use the specified packet size when sending. If the specified size is not supported for a media format, use the next closest value instead.

Finally, if this description is of type "pranswer" or "answer", follow the processing defined in [Section 5.11](#) below.

5.11. Applying an Answer

In addition to the steps mentioned above for processing a local or remote description, the following steps are performed when processing a description of type "pranswer" or "answer".

For each "m=" section, the following steps **MUST** be performed:

*If the "m=" section has been rejected (i.e., the <port> value is set to zero in the answer), stop any reception or transmission of media for this section, and, unless a non-rejected "m=" section is bundled with this "m=" section, discard any associated ICE components, as described in [[RFC8839](#)], [Section 4.4.3.1](#).

*If the remote DTLS fingerprint has been changed or the value of the "a=tls-id" attribute has changed, tear down the DTLS connection. This includes the case when the PeerConnection state is "have-remote-pranswer". If a DTLS connection needs to be torn down but the answer does not indicate an ICE restart or, in the case of "have-remote-pranswer", new ICE credentials, an error **MUST** be generated. If an ICE restart is performed without a change in the tls-id value or fingerprint, then the same DTLS connection is continued over the new ICE channel. Note that although JSEP requires that answerers change the tls-id value if and only if the offerer does, non-JSEP answerers are permitted to change the tls-id value as long as the offer contained an ICE restart. Thus, JSEP implementations that process DTLS data prior to receiving an answer **MUST** be prepared to receive either a ClientHello or data from the previous DTLS connection.

*If no valid DTLS connection exists, prepare to start a DTLS connection, using the specified roles and fingerprints, on any underlying ICE components, once they are active.

*If the "m=" section <proto> value indicates use of RTP:

-If the "m=" section references RTCP feedback mechanisms that were not present in the corresponding "m=" section in the offer, this indicates a negotiation problem and **MUST** result in an error. However, new media formats and new RTP header extension values are permitted in the answer, as described in [[RFC3264](#)], [Section 7](#) and [[RFC5285](#)], [Section 6](#).

- If the "m=" section has RTCP mux enabled, discard the RTCP ICE component, if one exists, and begin or continue muxing RTCP over the RTP ICE component, as specified in [[RFC5761](#)], [Section 5.1.3](#). Otherwise, prepare to transmit RTCP over the RTCP ICE component; if no RTCP ICE component exists because RTCP mux was previously enabled, this **MUST** result in an error.
- If the "m=" section has Reduced-Size RTCP enabled, configure the RTCP transmission for this "m=" section to use Reduced-Size RTCP, as specified in [[RFC5506](#)].
- If the direction attribute in the answer indicates that the JSEP implementation should be sending media ("sendonly" for local answers, "recvonly" for remote answers, or "sendrecv" for either type of answer), choose the media format to send as the most preferred media format from the remote description that is also locally supported, as discussed in Sections [6.1](#) and [7](#) of [[RFC3264](#)], and start transmitting RTP media using that format once the underlying transport layers have been established. If an SSRC has not already been chosen for this outgoing RTP stream, choose a unique random one. If media is already being transmitted, the same SSRC **SHOULD** be used unless the clock rate of the new codec is different, in which case a new SSRC **MUST** be chosen, as specified in [[RFC7160](#)], [Section 4.1](#).
- The payload type mapping from the remote description is used to determine payload types for the outgoing RTP streams, including the payload type for the send media format chosen above. Any RTP header extensions that were negotiated should be included in the outgoing RTP streams, using the extension mapping from the remote description. If the MID header extension has been negotiated, include it in the outgoing RTP streams, as indicated in [[RFC9143](#)], [Section 15](#). If the RtpStreamId or RepairedRtpStreamId header extensions have been negotiated and rid-ids have been established, include these header extensions in the outgoing RTP streams, as indicated in [[RFC8851](#)], [Section 4](#).
- If the "m=" section is of type "audio", and silence suppression was (1) configured for the send media format as a result of processing the remote description and (2) also enabled for that format in the local description, use silence suppression for outgoing media, in accordance with the guidance in [Section 5.2.3.2](#). If these conditions are not met, silence suppression **MUST NOT** be used for outgoing media.
- If simulcast has been negotiated, send the appropriate number of Source RTP Streams as specified in [[RFC8853](#)], [Section 5.3.3](#).

- If the send media format chosen above has a corresponding "rtx" media format or a FEC mechanism has been negotiated, establish a redundancy RTP stream with a unique random SSRC for each Source RTP Stream, and start or continue transmitting RTX/FEC packets as needed.
- If the send media format chosen above has a corresponding "red" media format of the same clock rate, allow redundant encoding using the specified format for resiliency purposes, as discussed in [[RFC8854](#)], [Section 3.2](#). Note that unlike RTX or FEC media formats, the "red" format is transmitted on the Source RTP Stream, not the redundancy RTP stream.
- Enable the RTCP feedback mechanisms referenced in the media section for all Source RTP Streams using the specified media formats. Specifically, begin or continue sending the requested feedback types and reacting to received feedback, as specified in [[RFC4585](#)], [Section 4.2](#). When sending RTCP feedback, follow the rules and recommendations from [[RFC8108](#)], [Section 5.4.1](#) to select which SSRC to use.
- If the direction attribute in the answer indicates that the JSEP implementation should not be sending media ("recvonly" for local answers, "sendonly" for remote answers, or "inactive" for either type of answer), stop transmitting all RTP media, but continue sending RTCP, as described in [[RFC3264](#)], [Section 5.1](#).

*If the "m=" section <proto> value indicates use of SCTP:

- If an SCTP association exists and the remote SCTP port has changed, discard the existing SCTP association. This includes the case when the PeerConnection state is "have-remote-pranswer".
- If no valid SCTP association exists, prepare to initiate an SCTP association over the associated ICE component and DTLS connection, using the local SCTP port value from the local description and the remote SCTP port value from the remote description, as described in [[RFC8841](#)], [Section 10.2](#).

If the answer contains valid bundle groups, discard any ICE components for the "m=" sections that will be bundled onto the primary ICE components in each bundle, and begin muxing these "m=" sections accordingly, as described in [[RFC9143](#)], [Section 7.4](#).

If the description is of type "answer" and there are still remaining candidates in the ICE candidate pool, discard them.

6. Processing RTP/RTCP

When bundling, associating incoming RTP/RTCP with the proper "m=" section is defined in [[RFC9143](#)], [Section 9.2](#). When not bundling, the proper "m=" section is clear from the ICE component over which the RTP/RTCP is received.

Once the proper "m=" section or sections are known, RTP/RTCP is delivered to the RtpTransceiver(s) associated with the "m=" section(s) and further processing of the RTP/RTCP is done at the RtpTransceiver level. This includes using the RID mechanism [[RFC8851](#)] and its associated RtpStreamId and RepairedRtpStreamId identifiers to distinguish between multiple encoded streams and determine which Source RTP stream should be repaired by a given redundancy RTP stream.

7. Examples

Note that this example section shows several SDP fragments. To accommodate RFC line-length restrictions, some of the SDP lines have been split into multiple lines, where leading whitespace indicates that a line is a continuation of the previous line. In addition, some blank lines have been added to improve readability but are not valid in SDP.

More examples of SDP for WebRTC call flows, including examples with IPv6 addresses, can be found in [[SDP4WebRTC](#)].

7.1. Simple Example

This section shows a very simple example that sets up a minimal audio/video call between two JSEP endpoints without using Trickle ICE. The example in the following section provides a more detailed example of what could happen in a JSEP session.

The code flow below shows Alice's endpoint initiating the session to Bob's endpoint. The messages from the JavaScript application in Alice's browser to the JavaScript in Bob's browser, abbreviated as "AliceJS" and "BobJS", respectively, are assumed to flow over some signaling protocol via a web server. The JavaScript on both Alice's side and Bob's side waits for all candidates before sending the offer or answer, so the offers and answers are complete; Trickle ICE is not used. The user agents (JSEP implementations) in Alice's and Bob's browsers, abbreviated as "AliceUA" and "BobUA", respectively, are both using the default bundle policy of "balanced" and the default RTCP mux policy of "require".

```
//          set up local media state
AliceJS->AliceUA: create new PeerConnection
AliceJS->AliceUA: addTrack with two tracks: audio and video
AliceJS->AliceUA: createOffer to get offer
AliceJS->AliceUA: setLocalDescription with offer
AliceUA->AliceJS: multiple onicecandidate events with candidates

//          wait for ICE gathering to complete
AliceUA->AliceJS: onicecandidate event with null candidate
AliceJS->AliceUA: get |offer-A1| from pendingLocalDescription

//          |offer-A1| is sent over signaling protocol to Bob
AliceJS->WebServer: signaling with |offer-A1|
WebServer->BobJS: signaling with |offer-A1|

//          |offer-A1| arrives at Bob
BobJS->BobUA: create a PeerConnection
BobJS->BobUA: setRemoteDescription with |offer-A1|
BobUA->BobJS: ontrack events for audio and video tracks

//          Bob accepts call
BobJS->BobUA: addTrack with local tracks
BobJS->BobUA: createAnswer
BobJS->BobUA: setLocalDescription with answer
BobUA->BobJS: multiple onicecandidate events with candidates

//          wait for ICE gathering to complete
BobUA->BobJS: onicecandidate event with null candidate
BobJS->BobUA: get |answer-A1| from currentLocalDescription

//          |answer-A1| is sent over signaling protocol
//          to Alice
BobJS->WebServer: signaling with |answer-A1|
WebServer->AliceJS: signaling with |answer-A1|

//          |answer-A1| arrives at Alice
AliceJS->AliceUA: setRemoteDescription with |answer-A1|
AliceUA->AliceJS: ontrack events for audio and video tracks

//          media flows
BobUA->AliceUA: media sent from Bob to Alice
AliceUA->BobUA: media sent from Alice to Bob
```

7.2. Detailed Example

This section shows a more involved example of a session between two JSEP endpoints. Trickle ICE is used in full trickle mode, with a bundle policy of "must-bundle", an RTCP mux policy of "require", and a single TURN server. Initially, both Alice and Bob establish an audio channel and a data channel. Later, Bob adds two video flows -- one for his video feed and one for screen sharing, both supporting FEC -- with the video feed configured for simulcast. Alice accepts these video flows but does not add video flows of her own, so they are handled as recvonly. Alice also specifies a maximum video decoder resolution.

```
//          set up local media state
AliceJS->AliceUA: create new PeerConnection
AliceJS->AliceUA: addTrack with an audio track
AliceJS->AliceUA: createDataChannel to get data channel
AliceJS->AliceUA: createOffer to get |offer-B1|
AliceJS->AliceUA: setLocalDescription with |offer-B1|

//          |offer-B1| is sent over signaling protocol to Bob
AliceJS->WebServer: signaling with |offer-B1|
WebServer->BobJS: signaling with |offer-B1|

//          |offer-B1| arrives at Bob
BobJS->BobUA: create a PeerConnection
BobJS->BobUA: setRemoteDescription with |offer-B1|
BobUA->BobJS: ontrack event with audio track from Alice

//          candidates are sent to Bob
AliceUA->AliceJS: onicecandidate (host) |offer-B1-candidate-1|
AliceJS->WebServer: signaling with |offer-B1-candidate-1|
AliceUA->AliceJS: onicecandidate (srflx) |offer-B1-candidate-2|
AliceJS->WebServer: signaling with |offer-B1-candidate-2|
AliceUA->AliceJS: onicecandidate (relay) |offer-B1-candidate-3|
AliceJS->WebServer: signaling with |offer-B1-candidate-3|

WebServer->BobJS: signaling with |offer-B1-candidate-1|
BobJS->BobUA: addIceCandidate with |offer-B1-candidate-1|
WebServer->BobJS: signaling with |offer-B1-candidate-2|
BobJS->BobUA: addIceCandidate with |offer-B1-candidate-2|
WebServer->BobJS: signaling with |offer-B1-candidate-3|
BobJS->BobUA: addIceCandidate with |offer-B1-candidate-3|

//          Bob accepts call
BobJS->BobUA: addTrack with local audio
BobJS->BobUA: createDataChannel to get data channel
BobJS->BobUA: createAnswer to get |answer-B1|
BobJS->BobUA: setLocalDescription with |answer-B1|

//          |answer-B1| is sent to Alice
BobJS->WebServer: signaling with |answer-B1|
WebServer->AliceJS: signaling with |answer-B1|
AliceJS->AliceUA: setRemoteDescription with |answer-B1|
AliceUA->AliceJS: ontrack event with audio track from Bob

//          candidates are sent to Alice
BobUA->BobJS: onicecandidate (host) |answer-B1-candidate-1|
BobJS->WebServer: signaling with |answer-B1-candidate-1|
BobUA->BobJS: onicecandidate (srflx) |answer-B1-candidate-2|
BobJS->WebServer: signaling with |answer-B1-candidate-2|

7.3. Early Transport Warmup Example

This example demonstrates the early-warmup technique described in [Section 4.1.10.1](#). Here, Alice's endpoint sends an offer to Bob's endpoint to start an audio/video call. Bob immediately responds with an answer that accepts the audio/video "m=" sections but marks them as sendonly (from his perspective), meaning that Alice will not yet send media. This allows the JSEP implementation to start negotiating ICE and DTLS immediately. Bob's endpoint then prompts him to answer the call, and when he does, his endpoint sends a second offer, which enables the audio and video "m=" sections, and thereby bidirectional media transmission. The advantage of such a flow is that as soon as the first answer is received, the implementation can proceed with ICE and DTLS negotiation and establish the session transport. If the transport setup completes before the second offer is sent, then media can be transmitted by the callee immediately upon answering the call,

minimizing perceived post-dial delay. The second offer/answer exchange can also change the preferred codecs or other session parameters.

This example also makes use of the "relay" ICE candidate policy described in [Section 3.5.3](#) to minimize the ICE gathering and checking needed.

```
//          set up local media state
AliceJS->AliceUA: create new PeerConnection with "relay" ICE policy
AliceJS->AliceUA: addTrack with two tracks: audio and video
AliceJS->AliceUA: createOffer to get |offer-C1|
AliceJS->AliceUA: setLocalDescription with |offer-C1|

//          |offer-C1| is sent over signaling protocol to Bob
AliceJS->WebServer: signaling with |offer-C1|
WebServer->BobJS: signaling with |offer-C1|

//          |offer-C1| arrives at Bob
BobJS->BobUA: create new PeerConnection with "relay" ICE policy
BobJS->BobUA: setRemoteDescription with |offer-C1|
BobUA->BobJS: ontrack events for audio and video

//          a relay candidate is sent to Bob
AliceUA->AliceJS: onicecandidate (relay) |offer-C1-candidate-1|
AliceJS->WebServer: signaling with |offer-C1-candidate-1|

WebServer->BobJS: signaling with |offer-C1-candidate-1|
BobJS->BobUA: addIceCandidate with |offer-C1-candidate-1|

//          Bob prepares an early answer to warm up the
//          transport
BobJS->BobUA: addTransceiver with null audio and video tracks
BobJS->BobUA: transceiver.setDirection(sendonly) for both
BobJS->BobUA: createAnswer
BobJS->BobUA: setLocalDescription with answer

//          |answer-C1| is sent over signaling protocol
//          to Alice
BobJS->WebServer: signaling with |answer-C1|
WebServer->AliceJS: signaling with |answer-C1|

//          |answer-C1| (sendonly) arrives at Alice
AliceJS->AliceUA: setRemoteDescription with |answer-C1|
AliceUA->AliceJS: ontrack events for audio and video

//          a relay candidate is sent to Alice
BobUA->BobJS: onicecandidate (relay) |answer-B1-candidate-1|
BobJS->WebServer: signaling with |answer-B1-candidate-1|

WebServer->AliceJS: signaling with |answer-B1-candidate-1|
AliceJS->AliceUA: addIceCandidate with |answer-B1-candidate-1|

//          ICE and DTLS establish while call is ringing

//          Bob accepts call, starts media, and sends
//          new offer
BobJS->BobUA: transceiver.setTrack with audio and video tracks
```

```
BobUA->AliceUA:    media sent from Bob to Alice
BobJS->BobUA:      transceiver.setDirection(sendrecv) for both
                   transceivers
BobJS->BobUA:      createOffer
BobJS->BobUA:      setLocalDescription with offer

//                |offer-C2| is sent over signaling protocol
//                to Alice

8. Security Considerations

The IETF has published separate documents [[RFC8827](#)] [[RFC8826](#)] describing the security architecture for WebRTC as a whole. The remainder of this section describes security considerations for this document.

While formally the JSEP interface is an API, it is better to think of it as an Internet protocol, with the application JavaScript being untrustworthy from the perspective of the JSEP implementation. Thus, the threat model of [[RFC3552](#)] applies. In particular, JavaScript can call the API in any order and with any inputs, including malicious ones. This is particularly relevant when one considers the SDP that is passed to `setLocalDescription`. While correct API usage requires that the application pass in SDP that was derived from `createOffer` or `createAnswer`, there is no guarantee that applications do so. The JSEP implementation **MUST** be prepared for the JavaScript to pass in bogus data instead.

Conversely, the application programmer needs to be aware that the JavaScript does not have complete control of endpoint behavior. One case that bears particular mention is that editing ICE candidates out of the SDP or suppressing trickled candidates does not have the expected behavior: implementations will still perform checks from those candidates even if they are not sent to the other side. Thus, for instance, it is not possible to prevent the remote peer from learning your public IP address by removing server-reflexive candidates. Applications that wish to conceal their public IP address **MUST** instead configure the ICE agent to use only relay candidates.

9. IANA Considerations

This document has no IANA actions.

Appendix A. SDP ABNF Syntax

For the syntax validation performed in [Section 5.8](#), the following list of ABNF definitions is used:

Attribute	Reference
ptime	Section 6 of [RFC4566]
maxptime	Section 6 of [RFC4566]
rtpmap	Section 6 of [RFC4566]
recvonly	Section 9 of [RFC4566]
sendrecv	Section 9 of [RFC4566]
sendonly	Section 9 of [RFC4566]
inactive	Section 9 of [RFC4566]
fntp	Section 9 of [RFC4566]
rtcp	Section 2.1 of [RFC3605]
setup	Section 4 of [RFC4145]
fingerprint	Section 5 of [RFC8122]
rtcp-fb	Section 4.2 of [RFC4585]
extmap	Section 7 of [RFC5285]
mid	Section 4 of [RFC5888]
group	Section 5 of [RFC5888]
imageattr	Section 3.1 of [RFC6236]
extmap (encrypt option)	Section 4 of [RFC6904]

Attribute	Reference
candidate	Section 5.1 of [RFC8839]
remote-candidates	Section 5.2 of [RFC8839]
ice-lite	Section 5.3 of [RFC8839]
ice-ufrag	Section 5.4 of [RFC8839]
ice-pwd	Section 5.4 of [RFC8839]
ice-options	Section 5.6 of [RFC8839]
msid	Section 3 of [RFC8830]
rid	Section 10 of [RFC8851]
simulcast	Section 5.1 of [RFC8853]
tls-id	Section 4 of [RFC8842]

Table 1: SDP ABNF References

Acknowledgements

Harald Alvestrand, Taylor Brandstetter, Suhas Nandakumar, and Peter Thatcher provided significant text for this document. Bernard Aboba, Adam Bergkvist, Jan-Ivar Bruaroey, Dan Burnett, Ben Campbell, Alissa Cooper, Richard Ejzak, Stefan Håkansson, Ted Hardie, Christer Holmberg, Andrew Hutton, Randell Jesup, Matthew Kaufman, Anant Narayanan, Adam Roach, Robert Sparks, Neil Stratford, Martin Thomson, Sean Turner, and Magnus Westerlund all provided valuable feedback on this document.
