A YANG Data Model for Network Interconnect Tester Management

Abstract

This document introduces new YANG model for use in network interconnect testing containing modules of traffic generator and traffic analyzer.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at https://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on 28 April 2022.

Table of Contents

1. Introduction

There is a need for standard mechanism to allow the specification and implementation of the transactions part of network tests. The mechanism should allow the control and monitoring of the data plane traffic in a transactional way. This document defines two YANG modules for test traffic generator and analyzer.

The YANG modules in this document conform to the Network Management Datastore Architecture (NMDA) defined in RFC 8342.

1.1. Terminology

1.1.1. Definitions and Acronyms

DUT: Device Under Test

TA: Traffic Analyzer

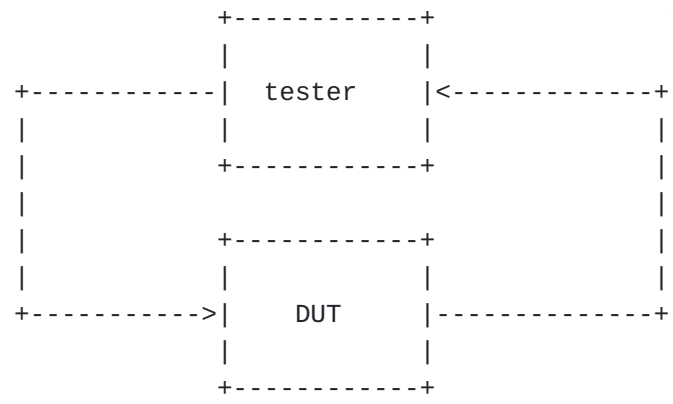
TG: Traffic Generator

1.1.2. Tree Diagram

For a reference to the annotations used in tree diagrams included in this document, please see YANG Tree Diagrams [RFC8340].

1.2. Problem Statement

Network interconnect tests require active network elements part of the tested network that generate test traffic and network elements that analyze the test traffic at one or more points of its path. A network interconnect tester is a device that can either generate test traffic, analyze test traffic or both. Here is a figure borrowed from [RFC2544] representing the horseshoe test setup topology consisting of a single tester and a single DUT connected in a network interconnect loop.



This document attempts to address the problem of defining YANG model of a network interconnect tester that can be used for development of vendor independent network interconnect tests and utilize the advantages of transactional management using standard protocols like NETCONF.

1.3. Objectives

This section describes some of the design objectives for the model. It should:

* provide means to specify the generated traffic as streams of cyclic sequence of bursts with configurable frame size, frame data, interframe gap and interburst gap.

* have a mandatory single stream mode and optional multi stream mode.

* provide means for configuration of traffic streams with static frame data where frames with identical frame data are sent during the lifetime of the stream.

*provide means for configuration of traffic streams with dynamic frame data where frames contain fields with dynamic data like generation time and sequence number.

*allow third parties to augment the base module with alternative dynamic fields of frame data extensions.

*provide means for realtime synchronization and orchestration of the generated streams.

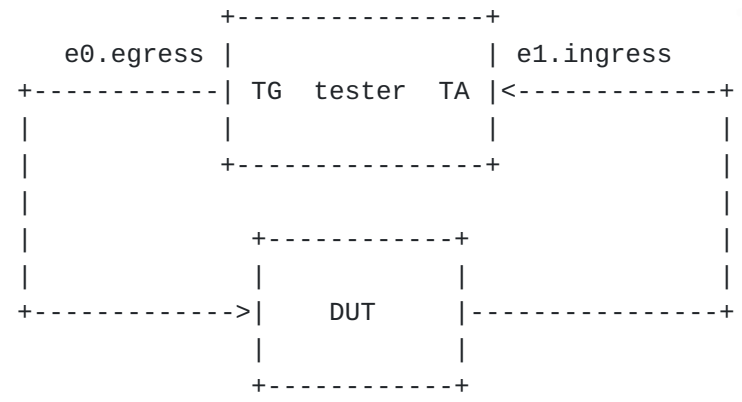
*provide counters for received test traffic frames and octets.

*provide latency statistic in the case of test traffic with dynamic frame data that includes timestamp.

*provide sequence number errors in the case of test traffic with dynamic frame data that includes sequence number.

1.4. Solution

The proposed model splits the design into 2 modules - 1) Traffic Generator module (TG), 2) Traffic Analyzer module (TA). The modules are implemented as augmentations of the ietf-interfaces [RFC8343] module adding configuration and state data that models the functionality of a network interconnect tester. The TA and TG modules concept is illustrated with the following diagram of a tester with two interfaces (named e0 and e1) connected in a loop with single DUT:



2. Using the network interconnect tester model

Basic example of how the model can be used in transactional network test program to control the testers part of a network and report counter statistics and timing measurement data is presented in Appendix A. All example cases present the configuration and state data from a single test trial. The search algorithm logic that operates to control the trial configuration is outside the scope of

this document. One of the examples demonstrates the use of the [RFC2544] defined testframe packet.

3. Traffic Generator Module Tree Diagram

<CODE ENDS>

7. IANA Considerations

This document registers two URIs and two YANG modules.

7.1. URI Registration

This document registers two URIs in the IETF XML registry [RFC3688]. Following the format in RFC 3688, the following registration is requested to be made:

URI: urn:ietf:params:xml:ns:yang:ietf-traffic-generator
URI: urn:ietf:params:xml:ns:yang:ietf-traffic-analyzer

Registrant Contact: The IESG.

XML: N/A, the requested URI is an XML namespace.

7.2. YANG Module Name Registration

This document registers two YANG module in the YANG Module Names registry YANG [RFC6020].

name: ietf-traffic-generator
namespace: urn:ietf:params:xml:ns:yang:ietf-traffic-generator
prefix: nttg
reference: RFC XXXX

name: ietf-traffic-analyzer
namespace: urn:ietf:params:xml:ns:yang:ietf-traffic-analyzer
prefix: ntta
reference: RFC XXXX

8. Security Considerations

The YANG modules defined in this document are designed to be accessed via the NETCONF protocol RFC 6241 [RFC6241]. The lowest NETCONF layer is the secure transport layer and the mandatory to implement secure transport is SSH RFC 6242 [RFC6242]. The NETCONF access control model RFC 6536 [RFC6536] provides the means to restrict access for particular NETCONF users to a pre-configured subset of all available NETCONF protocol operations and content.

There are a number of data nodes defined in this YANG module which are writable/creatable/deletable (i.e. config true, which is the default). These data nodes may be considered sensitive or vulnerable in some network environments. Write operations (e.g. edit-config) to these data nodes without proper protection can have a negative

effect on network operations. These are the subtrees and data nodes and their sensitivity/vulnerability:

8.1. ietf-traffic-generator.yang

The ietf-traffic-generator YANG module controls a stateless traffic generator which is intended to be used for testing and verification purposes but can be used for malicious purposes like generating network traffic part of a Denial-of-Service (DoS) attack. This should be taken into consideration when granting write access to the following container and descendant data nodes:

*/if:interfaces/if:interface/nttg:traffic-generator

8.2. ietf-traffic-analyzer.yang

The ietf-traffic-analyzer YANG module controls a traffic analyzer which is designed for use in testing and verification but can be used for reading information contained in packets sent and received on any of the interfaces on systems that implement the capture feature. This should be taken into consideration when granting read access to the following container and descendant data nodes:

*/if:interfaces/if:interface/ntta:traffic-analyzer/ntta:capture

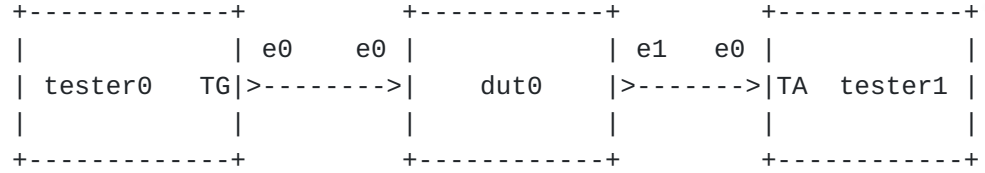
Appendix A. Examples

The following topology will be used for the examples in this section:



A.1. Basic Test Program

This pseudo code program orchestrates a network test and shows how the model can be used:

```
#Connect to network
net=connect("topology.xml")

# Configure DUTs and enable traffic-analyzers
net.node("dut0").edit( \
  "create /interfaces/interface[name='e0'] -- type=ethernetCsmacd")
net.node("dut0").edit(
  "create /interfaces/interface[name='e1'] -- type=ethernetCsmacd")
net.node("dut0").edit(
  "create /flows/flow[id='t0'] -- match/in-port=e0 "
  "actions/action[order='0']/output-action/out-port=e1")

net.node("tester1").edit(
  "create /interfaces/interface[name='e0']/traffic-analyzer")
net.commit()

#Get network state - before
before=net.get()

# Start traffic
net.node("tester0).edit(
  "create /interfaces/interface[name='e0']/traffic-generator -- "
  "frame-size=64 interframe-gap=20")

net.commit()

time.sleep(60)

# Stop traffic
net.node("tester1").edit("delete /interfaces/interface[name='e0']/"
                         "traffic-generator")
net.commit()

#Get network state - after
after=net.get()

#Report
sent_pkts=delta("tester0",before,after,
  "/interfaces/interface[name='e0']/statistics/out-unicast-pkts")

received_pkts=delta("tester1",before,after,
  "/interfaces/interface[name='e0']/statistics/in-unicast-pkts")

latency_max=absolute(after,
  "/interfaces/interface[name='e0']/traffic-analyzer/state/"
  "testframe-stats/latency/max")

#Cleanup
net.node("tester1").edit(
   "delete /interfaces/interface/traffic-analyzer")
```

```
net.node("dut0").edit("delete /flows")
net.node("dut0").edit("delete /interfaces")
net.commit()
```

A.2. Generating RFC2544 Testframes

In sec. C.2.6.4 Test Frames a detailed format is specified. The frame-data leaf allows full control over the generated frames payload.

```
...
net.node("tester1").edit(
  "merge /interfaces/interface[name='e0']/"
  "traffic-generator -- frame-data="
  "6CA96F0000026CA96F00000108004500"
  "002ED4A500000A115816C0000201C000"
  "0202C0200007001A0000010203040506"
  "0708090A0B0C0D0E0F101112")
...
```
