**SYSLOG YANG model**  
**draft-wildes-netmod-syslog-model-03**

#### Abstract

This document describes a data model for Syslog protocol which is used to convey event notification messages.

#### Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on March 22, 2015.

## [1. Introduction](#)

Operating systems, processes and applications generate messages indicating their own status or the occurrence of events. These messages are useful for managing and/or debugging the network and its services. The BSD Syslog protocol is a widely adopted protocol that is used for transmission and processing of the messages.

Since each process, application and operating system was written somewhat independently, there is little uniformity to the content of Syslog messages. For this reason, no assumption is made upon the formatting or contents of the messages. The protocol is simply designed to transport these event messages. No acknowledgement of the receipt is made.

Essentially, a Syslog process receives messages (from the kernel, processes, applications or other Syslog processes) and processes those. The processing involves logging to a local file, displaying on console, user terminal, and/or relaying to syslog processes on other machines. The processing is determined by the "facility" that originated the message and the "severity" assigned to the message by the facility.

We are using definitions of Syslog protocol from [[RFC3164](#)] in this draft.

### 1.1. Definitions and Acronyms

IP: Internet Protocol

IPv4: Internet Protocol version 4

IPv6: Internet Protocol version 6

UDP: User Datagram Protocol

VRF: Virtual Routing and Forwarding

### 2. Problem Statement

This document defines a YANG [[RFC6020](#)] configuration data model that may be used to monitor and control one or more syslog processes running on a system. YANG models can be used with network management agents such as NETCONF [[RFC6241](#)] to install, manipulate, and delete the configuration of network devices.

This module makes use of the YANG "feature" construct which allows implementations to support only those Syslog features that lie within their capabilities.

### 3. Design of the SYSLOG Model

The syslog model was designed by comparing various syslog features implemented by various vendors' in different implementations.

This draft addresses the common leafs between all vendors and creates a common model, which can be augmented with proprietary features, if necessary. The base model is designed to be very simple for maximum flexibility.

Syslog consists of message producers, a group level suppression filter, and message distributors. The following diagram shows syslog messages flowing from a message producer, through the group level suppression filter, and if passed by the group filter to message distributors where further suppression filtering can take place.

### Message Producers

### Group Level Suppression

### Message Distributors

The leaves in the base syslog model correspond to the group level suppression filter and each message distributor:

- console
- log file(s)
- user terminals
- remote server(s).

Optional features are used to specified fields that are not present in all vendor configurations.

#### 4.3. A SYSLOG Example

Requirement:

Enable global logging of two facilities:

```
kern - severity critical(1)  
auth - severity error(3)
```

Enable console logging of syslogs of severity  
critical(1)

Here is the example syslog configuration xml:

```
<rpc message-id="101" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">  
  <edit-config>  
    <target>  
      <running/>  
    </target>  
    <config>  
      <syslog xmlns="urn:ietf:params:xml:ns:yang:ietf-syslog">  
        <global-logging-action>  
          <logging-facilities>  
            <facility>syslogtypes:kern</facility><logging-  
severity>syslogtypes:critical</logging-severity>  
          </logging-facilities>  
          <logging-facilities>  
            <facility>syslogtypes:auth</facility><logging-  
severity>syslogtypes:error</logging-severity>  
          </logging-facilities>  
        </global-logging-action>  
        <console-logging-action>  
          <severity>syslogtypes:critical</severity>  
        </console-logging-action>  
      </syslog>  
    </config>  
  </edit-config>  
</rpc>  
  
<?xml version="1.0" encoding="UTF-8"?>  
<rpc-reply message-id="101" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">  
  <ok/>  
</rpc-reply>
```

## 5. Implementation Status

[Note to RFC Editor: Please remove this section before publication.]

This section records the status of known implementations of the Syslog YANG model at the time of posting of this Internet-Draft.

Cisco Systems, Inc. has implemented the proposed IETF Syslog model for the Nexus 7000 NXOS OS as a prototype, together with an augmentation model for operating system specific Syslog configuration features.

Five leaves were implemented in the base IETF model and three leaves were implemented in the NXOS specific augmentation model as follows:

Leaf XPATH	Sample NXOS CLI Command(s)
syslog:global-logging	logging level cron 2
syslog:console-logging	logging console 1
syslog:file-logging	logging logfile mylog.log 2 4096
syslog:terminal-logging	logging monitor 2
syslog:remote-logging	*logging server server.cisco.com 2 facility user use-vrf management *logging source-interface loopback 0
cisco-syslog:logging-timestamp-config	logging timestamp milli-seconds
cisco-syslog:origin-id-cfg	logging origin-id string abcdef
cisco-syslog:module-logging	logging module 1

\*The "logging server" and "logging source-interface" commands were combined into one base model leaf.

The description of implementations in this section is intended to assist the IETF in its decision processes in progressing drafts to RFCs.

## 6. Security Considerations

The YANG module defined in this memo is designed to be accessed via the NETCONF protocol [[RFC6241](#)] [[RFC6241](#)]. The lowest NETCONF layer is the secure transport layer and the mandatory-to-implement secure transport is SSH [[RFC6242](#)] [[RFC6242](#)]. The NETCONF access control model [[RFC6536](#)] [[RFC6536](#)] provides the means to restrict access for particular NETCONF users to a pre-configured subset of all available NETCONF protocol operations and content.

There are a number of data nodes defined in the YANG module which are writable/creatable/deletable (i.e., config true, which is the default). These data nodes may be considered sensitive or vulnerable in some network environments. Write operations (e.g., <edit-config>) to these data nodes without proper protection can have a negative effect on network operations.

TBD: List specific Subtrees and data nodes and their sensitivity/vulnerability.

Wildes, et al.

## **7. IANA Considerations**

This document registers a URI in the IETF XML registry [[RFC3688](#)] [[RFC3688](#)]. Following the format in [RFC 3688](#), the following registration is requested to be made:

URI: urn:ietf:params:xml:ns.yang:syslog

Registrant Contact: The IESG.

XML: N/A, the requested URI is an XML namespace.

This document registers a YANG module in the YANG Module Names registry [[RFC6020](#)].

name: syslog namespace: urn:ietf:params:xml:ns.yang:syslog  
prefix: syslog reference: RFC XXXX
